CVB Feed Table 2021

Chemical composition and nutritional values
of feedstuffs

March 2021

Internet: www.cvbdiervoeding.nl

CVB is an activity of the Foundation CVB

With respect to content the activity is carried out by Wageningen Livestock Research (WLR) and the Research Institute for Agriculture, Fisheries and Food (ILVO)

PREFACE

In comparison with the former edition of the CVB Feed Table in 2019 the following changes are made:

a. The data of two large research projects in which the energy value of high moisture industrial co-products and compound feedstuffs were studied were added to the already existing CVB dataset. Based on this extended dataset the calculation rules for 111 compound feedstuffs and 34 high moisture industrial co-products for growing pigs were updated.
b. Furthermore, 3 new high moisture industrial co-products are added to the CVB Feed Table. These products are pea fibre, liquid pea protein and pea creme.
c. In practice the starch content in wheat and wheat milling by-products are analysed based on the Ewers method (STAew) whereas the feed evaluation systems calculates with starch contents that are analysed using the amylase method (STAam). Therefore, in the past the relationship between STAew and STAam has been determined based on wheat and wheat milling by-products samples that were analysed on both STAew and STAam. The relationship between STAew and STAam for wheat and wheat by-products has recently been updated based on new information.
d. For 3 feedstuffs (wheat, lucerne silage and corn cob mix (CCM)) it appeared that in the former CVB Feed Table edition erroneous Co contents were presented. In this edition the correct Co concentrations are provided.

March 2021

CONTENTS

1. GENERAL INTRODUCTION

1.1 Reader manual

1.1.1 Outline of this publication

At first, an explanation is given for several subjects:

- Chemical composition of feedstuffs (Chapter 2)
- Feed evaluation systems for ruminants (Chapter 3), pigs (Chapter 4), poultry (Chapter 5), rabbits (Chapter 6) and horses (Chapter 7)
- Overview of relevant literature (Chapter 8)
- List of abbreviations (Chapter 9)

Thereafter, Chapter 10 contains the main part of this publication, the information on separate feedstuffs (also see paragraph 1.1.2).

1.1.2 Product information

This Feed Table provides in Chapter 10 information concerning the composition and nutritional value for ruminants, pigs, poultry, rabbits and horses. Depending on the animal species, the following feedstuffs are included:

- Compound feedstuffs
- High moisture industrial co-products
- Roughages and related products
- Miscellaneous

1.1.2.1 Compound feedstuffs and high moisture industrial co-products

For these feedstuffs, all available information is displayed on two pages (front and back of a product sheet). The products are arranged alphabetically. Per product the following data are given:

- Chemical composition: Weende analysis components, structural and non-structural carbohydrates, minerals and trace elements (with standard deviation, when available);
- Contents of fatty acids and amino acids;
- Fermentation products;
- Contents of digestible nutrients and feeding values according to the CVB feed evaluation systems for the animal species mentioned in paragraph 1.1.2.

The contents and values of compound feedstuffs are presented on product basis; those of high moisture industrial co-products on dry matter basis.

1.1.2.2 Roughages and related products

For these feedstuffs the same information is provided (where available) in the same manner.
Also for these feedstuffs the contents and values are given on dry matter basis.

1.1.2.3 Miscellaneous

This concerns mineral feedstuffs, for which the composition is stated, and some pure substances (e.g., organic acids); for both groups relevant feeding value characteristics are given.

1.1.2.4 Points of attention for feedstuffs

With several feedstuffs specific points of attention apply. These points of attention, if applicable to a feedstuff can be found underneath the second page of the productsheet of that particular feedstuff.

1.2 Encoding of feedstuffs

For the purpose of automated data processing, the feedstuffs have been given a code number. The code number consists of four numbers of four, three, one, and one digit(s), respectively. The numbers are separated by a dot (.), and twice a dash (/), respectively. Further explanation of the coding system is given in document RD001 on the CVB-website www.cvbdiervoeding.nl.

1.3 Variability of feedstuffs and feed evaluation

In many feedstuffs (mainly, but not exclusively, roughages) there is considerable variation in the content of one or more nutrients. Especially with varying amounts of crude fibre, this will also result in varying digestibility of other nutrients. Therefore, fluctuations in feeding value may be larger than expected based on variations in nutrient contents.
One of the key competences of CVB is the developing of relationships between variation in chemical composition and variation in nutrient digestibility. More information is provided in the description of the separate feed evaluation systems.

It is emphasized that the product information in this table can only be regarded as a guideline, and not as a faultless representation of contents of the feedstuffs mentioned. To determine the correct contents of a certain batch of a feedstuff, laboratory analysis of samples of that batch is required. This is especially the case for feedstuffs where the standard deviation (sdc) is high.
Furthermore, it is pointed out that in many cases in this table, recalculations have been made from product-based to dry matter-based contents and values, and vice versa. When recalculating the feeding values of the individual feedstuffs, small deviations may occur due to rounding of values.

2 CHEMICAL COMPOSITION OF FEEDSTUFFS

2.1 General

In this chapter, concise information is given on the chemical composition, as stated for the individual feedstuffs. More elaborate information is given in document RD002 on the CVB-website www.cvbdiervoeding.nl

2.2 Origin of data

Since 1985, CVB collects on a continuous and systematic basis data concerning the chemical composition and digestibility of feedstuffs. Before data on chemical composition of feedstuffs are entered in the CVB database, the data are checked for several criteria, like:

- The analytical method(s) used.
- Whether the analytical data fall within the range established for each chemical parameter per feedstuff.

The composition of the feedstuffs in the Feed Table are, as much as possible, based on information from the CVB database. For some chemical parameters, in a limited number of cases, literature values have been used.
The feedstuff itself also has to meet certain criteria, before it can be included in one of the CVB tables. These criteria concerning the nature (and production method) of the feedstuff, the reliability of the available analytical results, the use of the feedstuff and information on the digestibility of chemical components for at least one animal species.

When analytical results of Weende components are available for ten or more samples, the variability (sdc) is added to the mean content. For amino acids, macro-minerals, and micro-minerals, sdc is given when at least five analytical results are available.
When no content is known for a nutrient, the table shows a dash (-). When a value 0 is given in the table, the content of this nutrient is zero.

2.3 Explanation of reported chemical parameters

2.3.1 Crude protein (CP)

To determine the crude protein content, the analyzed nitrogen (N) content is multiplied by a factor 6.25. The crude protein contents in this table are practically all based on the N content analysed according to the Kjeldahl method. Because of the polluting effects of the chemicals used in this method, laboratories nowadays switch to the method according to Dumas. In this method nitrate is included in the determination; this is only to a very limited extent the case when the Kjeldahl method in used. For feedstuffs rich in nitrate (e.g., grass and alfalfa meal), the Dumas procedure therefore results in higher analysed N contents. In other feedstuffs, the difference between the two methods is so small that data from both methods may be combined in one dataset. In this Feed Table we only included Dumas values if this resulted in more robust mean values.

2.3.2 Starch (STAam)

In the CVB feed evaluation systems, the starch content (where appropriate) is determined by using the enzyme amyloglucosidase (STAam) (ISO/DIS 15914, 2004), and not according to the polarimetric method of Ewers (STAew) (ISO/DIS 6493, 2000), as used in the past in the Netherlands, and still in many other countries). Because in practise in most cases the polarimetric method is used, the CVB database contains for almost all feedstuffs more STAew records than STAew records. The CVB database contains for some, but not yet for all, feedstuffs sufficient STAam data to calculate a representative mean value. When insufficient STAam data are available in the database, (feedstuff-specific) regression equations have been used to estimate STAam from STAew. These equations are based on samples, in which both STAam and STAew were determined. Subsequently, the relation between STAam and STA ew was determined by means of regression analysis. The product sheets of this Feed Table contain the calculated STAam values based on the regression equation presented below. In cases were no regression equations were developped but analyzed STAam data was available the mean of the analysed STAam is presented. The estimation equations are meant to calculate STAam from STAew (on dry matter basis). Equations without a constant may also be used directly (on product base). These regression equations may also be used in practice to calculate STAam from STAew. However, it is recommended to determine STAam according to the official analytical procedure. For some feedstuffs rich in starch (e.g. peas and horse beans) no regression equations were developped as (part of the) STAew is an artefact. This is also true for feestuffs such as beet pulp, citrus pulp, and oil containing seeds and their by-products.

Below, the derived estimation equations are given for the various product categories. To be able to use these equations in practice, the minimum and maximum STAew in the database underlying the equations are also given, together with the explained variance and the standard error of the estimation of STAam from STAew.

The regression equations have also been included in the on-line 'CVB feeding value calculator'.

2.3.3 Crude fat (CFAT and CFATh)

The type of crude fat (CFAT or CFATh) to be used for the calculation of energy values for animals depends on the one hand on the type of energy evaluation system and on the other hand on the type of feedstuff. For the calculation of of metabolizable energy for broilers (MEbr), since 2011 for all feedstuffs, the MEbr calculated using the crude fat value that is based on a method where the sample is hydrolysed with acid before analysis on crude fat (CFATh; Method B). For the calculation of NE_{2015} values for pigs also CFATh analysis values are used. For the VEM/VEVI calculation for ruminants, the MEpo and MEla for, respectively, adult poultry and laying hens, the MErab for rabbits, and the EWpa for horses in most cases the crude fat value is used that is based on a crude fat analysis with petroleum ether as an extraction solvent, without a preceding acid hydrolysis step (CFAT; Method A). For these feedstuffs, there is (generally speaking) a small and relatively constant difference between the fat analysis without and with acid hydrolysis.
For certain feedstuffs (e.g., feedstuffs of animal origin, maize gluten feed, many high moisture industrial co-products; see also paragraph 2.4) this is not the case; the energy value is then based on the fat content analysed after acid hydrolysis. An overview of the feedstuffs (only first two numbers of the code number (see paragraph 1.2)) is given in the Table below for which the CFATh value is used for calculation of the energy values for ruminants, horses, rabbits, adult poultry and laying hens:

Overview of feedstuffs (presented as the code number) for which the CFATh value is used for calculation of the energy values for ruminants, horses, rabbits, adult poultry and laying hens

1000.304	1005.324	4001.231	8007.000

1002.212	1010.234	4001.664	8010.000
1002.240	1010.236	4006.634	8012.000
1002.308	1010.310	8001.001	8023.000
1002.310	1010.612	8001.003	9001.315
1002.517	1010.689	8003.629	9011.001
1002.629	4001.203	8004.000	9011.002
1005.313	4001.223	8005.000	

For many compound feedstuffs, the Feed Table gives the contents of both CFAT (crude fat without acid hydrolysis) and CFATh (crude fat after acid hydrolysis). CVB has performed comparative analyses in a large number of samples of individual feedstuffs to calculate the mean difference between the two methods in order to report mutual consistent CFAT and CFATh contents. The CFAT content on the product sheets is based on analyses from the CVB database; the CFATh content is usually derived from the mean of the analysed CFAT content adding the observed difference between CFATh and CFAT to this CFAT value in order to obtain a CFATh value that is consistent with the reported mean analysed CFAT value.

2.3.4 Nitrogen-free extract (NFE and NFEh)

From the Feed Table 2004 onwards, two ‘NFE contents’ are distinguished: NFE and NFEh. To calculate the NFE content, moisture, ASH, CP, CF and CFAT are subtracted from DM. In the calculation of NFEh, the CFATh content is subtracted instead of the CFAT content.

2.3.5 Cell wall parameters

In the Netherlands, as in most other European countries, the crude fibre (CF) content is mostly used as criterion for the content of cell wall components in practical animal nutrition. In document

RD003 on the website (www.cvbdiervoeding.nl) it is described which cell wall components are actually determined with this method. A better characterisation of cell wall components is obtained with the Van Soest analysis (see document RD003), in which the contents of NDF, ADF (or NDADF) and ADL are determined.
From statistical analysis on sample data on CF, NDF, ADF and/or ADL in the CVB database it appeared that for many feedstuffs there is a reasonable or good relationship between the CF content and the Van Soest parameters (mainly ADF). Because the CVB database usually contains a large number of analytical data for CF for each feedstuff, reliable mean values can be calculated. For the Van Soest parameters, the number of analytical data is relatively small; the stated Van Soest parameters are (where necessary and possible) calculated with the estimation equations developed by CVB. A correct estimation of the NDF content is important for a correct protein validation of the feedstuffs in the framework of the DVE/OEB system 2007 (see paragraph 3.4).

2.3.6 Inositol bound phosphorus (IP)

The stated content of inositol bound phosphorus (IP) is a calculated value: the content of total P is multiplied by the percentage of 'IP/P' : 100. The percentage 'IP/P' for individual feedstuffs is based on analysis of a number of samples in which (total) P and inositol bound P have been determined.

2.3.7 Electrolyte balance (EB) and Cation-anion difference (CAD)

The CAD is often used in practical ruminant feeding. The EB is mainly used for monogastric animals. EB and CAD are relevant parameters for the regulation of the pH of the blood. EB and CAD are calculated according to the following equations:

EB (in meq per kg) = 43.5 Na + 25.6 K - 28.2 Cl

CAD (in meq per kg) = 43.5 Na + 25.6 K - 28.2 Cl - 62.4 (S-i + S-o)

For compound feedstuffs, the EB and CAD values are expressed in meq per kg of product. For high moisture industrial co-products and roughages the EB and CAD values are given in meq per kg DM.

In some feedstuffs, the content of inorganic sulphur (S-i) may vary strongly between batches. This can be seen from the standard deviation (if stated) in S-i content. For certain feedstuffs (e.g., whey powders, molasses, vinasse, and other products from fermentation processes) it is known that the S-i content may vary strongly. In general, high moisture industrial co-products to which acids have been added for concervation purposes require extra attention. An example of an added acid is sulphuric acid; if these feedstuffs containing added sulphuric acid are used to feed monogastric animals the used of the CAD equation is advised.

2.4 Analytical methods

Table 2.1 lists the analytical methods used to determine the chemical parameters as mentioned in the CVB Feed Table. In the previous English 2011 Feed Table edition of CVB references of analytical methods were provided (the so called 'WM' references) that were described in a document of the former Product Board of Animal Feed. These WM references were largely based on EC regulations. In this edition direct EC regulation references are given instead of the WM references. Analysis results will be added to the CVB database in case:

- Analyses are carried out by a certified lab;
- Analyses are carried out according the EC Regulation 152/2009, or the ISO norms specified in the EC Regulation, or adapted methods yielding equivalent results (as shown by the accreditation of the laboratory).

Table 2.1 Overview analytical methods

Analysis	Description	Reference
Dry matter (DM)	Dry feedstuffs The residue after drying at 103 °C until constant weight, except for sugar containing feeds (with > 4% sugars), in which the sample is dried until constant weight at 80 °C under vacuum Moisture rich feedstuffs The residue after drying under vacuum at 80 °C until constant weight. The sample is spread out over a sand bed.	EC Regulation 152/2009; ISO 6496, 1999
Crude ash (ASH)	The residue after incineration at 550 °C	EC Regulation 152/2009; ISO 5984, 2002
Crude protein (CP)	Nitrogen according to Kjeldahl or (except for leaf-rich products such as grass or alfalfa meal) Dumas, multiplied by 6.25	Kjeldahl: EC Regulation 152/2009; ISO 5983-1, 2009 and ISO 5983-2, 2009 Dumas: EC Regulation 152/2009 ISO 16634, 2008 and ISO 16634, 2009
Crude fat (CFAT; CFATh)	The fat is extracted with petroleum ether, boiling range 40 to 60 °C, dried and weighed (= CFAT). Although, according to the EG method, since 1999 crude fat should be analyzed with acid hydrolysis in all feeds (= CFATh) this is not common practice. Therefore, CVB has determined CFAT with and without acid hydrolysis for each feedstuff, to calculate CFATh from CFAT by regression. For gluten products, soy and potato protein, feeds of animal origin, and some wet feedstuffs, CFATh has been analyzed already for many years. In these cases, only the CFATh content is reported, and feeding values should be calculated using this parameter. In the CVB protocols for the execution of digestibility trials, it is prescribed to determine the crude fat content of feed and faeces after pre-treatment with hydrochloric acid (when determining crude fat digestibility).	EC Regulation 152/2009; ISO 6492, 1999
Crude fibre (CF)	The residue after boiling in diluted sulphuric acid and diluted caustic potash is incinerated at approximately 500 °C; the loss after incineration is the CF fraction. For fat rich products (> 100 g/kg), pre-treatment with petroleum ether, boiling range 40 to 60 °C, is required to remove the fat. Products containing more than 5% $CaCO_3$ should be pre-treated with hydrochloric acid.	EC Regulation 152/2009; ISO 6865, 2000
Nitrogen-free extract (NFE and NFEh)	The content of N-free extract is not analyzed, but calculated: NFE(h) = 1000 – (moisture + ASH + CP + CFAT(h) + CF). This implies that all inaccuracies	N.A.

Analysis	Description	Reference
	in the analyses of the five components accumulate in the NFEh content. In some cases this may result in a negative NFEh content. A negative NFEh content may also occur if the factor 6.25 for calculating crude protein from N is not entirely correct for a specific feedstuff.	
Starch (STAew)	The reported STAew contents are based on a polarimetric method, according to the method of Ewers.	EC Regulation 152/2009; ISO 6493, 2000
Starch (STAam)	To determine starch using amyloglucosidase, a new analytical protocol is available: the sample is extracted with 40% ethanol (to remove the sugar fraction), after which the starch in the residue is gelatinized with DMSO and hydrolyzed with amyloglucosidase. The glucose released is then analysed with the enzyme hexokinase.	ISO/DIS 15914, 2004
Glucose oligo-saccharides (GOS)	The amount of GOS (starch fragments up to approximately 10 glucose units) is determined by analysing the amount of glucose units in two samples, as follows: a. Direct analysis of the amount of glucose units according to the Luff-Schoorl method in the 40% ethanol soluble fraction b. Analysis of the amount of glucose units, according to the Luff-Schoorl method in the 40 % ethanol soluble fraction, after incubation with excess amyloglucosidase The content of GOS is: b - a *For this analysis the total content of SUG is determined ass well.*	Smits et al., 1994
Combined determination of STAam and Glucose oligosaccharides (GOS) **(For the individual feedstuffs in Chapter 10, if GOS is present, the sum of STAam and GOS is given as STAtot)**	The combined determination of the content of STAam and GOS is performed by analyzing the content of reducing equivalents (expressed as glucose units) in two samples of the feedstuff: a. Direct determination of the content of reducing equivalents according to the method Luff-Schoorl in the 40% ethanol soluble fraction. This gives the SUG content b. Determination of the content of reducing equivalents, according to the method Luff-Schoorl in a *watery* solution of the feedstuff, in which, prior to analysis, all starch and glucose oligosaccharides are converted into free glucose by means of amyloglucosidase, according to ISO/DIS 15914. The difference with ISO/DIS 15914 is, that no extraction of the feedstuff with 40% ethanol takes place prior to the gelatinization with DMSO. After incubation with amyloglucosidase, an inversion takes place according to the method Luff Schoorl, followed by determination of the content of reducing	See document RD004 on the website www.cvbdiervoeding.nl

Analysis	Description	Reference
	equivalents. This analysis gives the sum of STAam, GOS and SUG The content of STAam + GOS is: b - a (see document RD005 on the website www.cvbdiervoeding.nl). The combined determination of STAam and GOS is only relevant for the calculation of the net energy value of (wet) feedstuff for pigs, and may only be applied when it is likely that the starch is digested well by enzymes of the animal itself (in other words, when DCiSTA = 100%).	
Sugars (SUG)	The content of reducing sugars, present in the 40% ethanol soluble fraction, after inversion, determined according to Luff-Schoorl.	71/250/EEC
Neutral Detergent Fibre (NDF)	After boiling in a neutral detergent, the residue is incinerated. The loss after incineration is the NDF content.	NEN-EN-ISO 16472:2006
Acid Detergent Fibre (ADF)	After boiling in an acid detergent (detergent in 0.5 M H_2SO_4), the residue is incinerated. The loss after incineration is the ADF content.	NEN-EN-ISO 13906:2008
Acid Detergent Lignin (ADL)	The ADF is treated with 72% H_2SO_4 (12 Mol H_2SO_4/l) during 3 hours at room temperature. Subsequently, the residue is incinerated and the loss after incineration is the ADL content.	
Non-Starch Polysaccha-rides (NSPh)	The content of NSPh is not analysed, but calculated: NSP = 1000 – (moisture + ASH + CP + CFATh + STAam + GOS + CF_DI*SUG + Glycerol + 0.92*LA + 0.5*(AC + PR + BU). This implies that all inaccuracies in the analyses of the eleven components accumulate in the NSP content. In some cases this may result in a negative NSP content. A negative NSPh content may also occur if the factor 6.25 for calculating crude protein from N is not entirely correct for a specific feedstuff.	N.A.
Residual Non-Starch Polysaccharide s (RNSP)	The content of RNSP is not analysed, but calculated: RNSP = 1000 – (moisture + ASH + CP + CFAT + STAam + GOS + CF_DI*SUG + Glycerol + 0.92*LA + 0.5*(AC + PR + BU) + NDF). This implies that all inaccuracies in the analyses of the eleven components accumulate in the RNSP content. In some cases this may result in a negative RNSP content. A negative RNSP content may also occur if the factor 6.25 for calculating crude protein from N is not entirely correct for a specific feedstuff. RNSP is a parameter of importance for the protein evaluation of feedstuffs for ruminants. For most of	N.A.

Analysis	Description	Reference
	the ruminant feedstuffs CFAT is the prescribed method; for feedstuffs where CFATh is the prescribed method the CFATh value instead of the CFAT should be subtracted.	
Potassium (K)	Atomic Absorption Spectroscopy (AAS) or Atomic Emission Spectroscopy (AES) determined content after incineration and treatment of the ashes with hydrochloric acid.	ISO 7485:2000; ISO 6869:2000
Sodium (Na)	Atomic Absorption Spectroscopy (AAS) or Atomic Emission Spectroscopy (AES) determined content after incineration and treatment of the ashes with hydrochloric acid.	ISO 7485:2000; ISO 6869:2000
Phosphorus (P)	Spectral-photometrically determined content after destruction.	EC Regulation 152/2009;ISO 6491, 1998
Magnesium (Mg)	Atomic Absorption Spectroscopy (AAS) determined concent after incineration and treatment of the ashes with hydrochloric acid.	EC Regulation 152/2009;ISO 6869, 2012
Sulphur (S)	In this table two sulphur determination methods are given for dry compound feedstuffs and high moisture industrial co-products: • inorganic S (S-i) This is analysed as sulphate (SO_4) by extracting the sample with HCl, centrifuging and filtering, after which the amount of sulphate is measured, using ion chromatography, followed by suppressed conductivity detection. The S content in sulphate is calculated by dividing by 3: $S/SO_4 = 32/(32+4*16) = 1/3$. • organic S (S-o) This is calculated from the S contents of the amino acids MET and CYS. The calculation is as follows: S-o = 32/149* MET + 32/120 * CYS in which: 32 = atomic mass of S 149 = molecular mass of MET 120 = molecular mass of CYS MET = MET content in g/kg CYS = CYS content in g/kg N.B. It is assumed that the amount of sulphur in other organic compounds is (very) limited.	N.A.
Remaining macro- and micro-elements	Depending on the element and (mainly) the concentration in the feedstuffs, various methods are used.	EC Regulation 152/2009;ISO 6869, 2012
Total inositol bound phosphorus (IP)	The content of P that is released after long-term incubation with excess microbial phytase, multiplied with a factor 1.25. If, for a certain feedstuff, it is experimentally shown that this inositol bound P	Bos et al., 1993

Analysis	Description	Reference
	content differs only slightly from the IP-6 content as determined by HPLC, or if this is likely (based on other information), all HPLC based analytical results have also been incorporated in the calculation of the content of Total inositol-P.	
Amino acids	Most amino acids are determined using an amino acids analyzer, after 22 hours of hydrolysis with 6N hydrochloric acid at 160°C. The amino acids CYS, MET and TRP are analyzed in separate runs. The S-containing amino acids CYS and MET are oxidized with hydrogen peroxide and per-formic acid prior to the hydrolysis. TRP first undergoes an alkaline hydrolysis and is then analyzed by HPLC.	EC Regulation 152/2009;ISO 13903:2005
Fatty acids	The fatty acids composition is analyzed by gas chromatography after alkaline hydrolysis of the fat fraction, followed by methylation. The contents of individual fatty acids are expressed in g/kg product or g/kg DM. The contents are calculated from the proportion of a fatty acid in the total amount of fatty acids and an estimated proportion of the total fatty acids in the crude fat fraction. This percentage is also stated.	ISO/TS 17764-1:2002 and ISO/TS 17764-2:2002
Volatile fatty acids (VFA), ethanol (ETH), lactic acid (LA), acetic acid (AC), propionic acid (PR) and buteric acid (BU)	The contents of the volatile fatty acids acetic acid (AC), propionic acid (PR), and butyric acid (BU), as well as the contents of ethanol (ETH) and lactic acid (LA) are determined by HPLC, in an extract of the fresh product, and then calculated to dry matter.	FAO Animal Production And Health manual: Quality assurance for Animal feed analysis laboratories, J. Baltrup et al., Rome, 2011.

2.5 Classification of carbohydrates

In present-day animal nutrition, more attention is given to the diversity of carbohydrates present in feedstuffs. More information is provided in document RD005 on the CVB website www.cvbdiervoeding.nl.

3 FEED EVALUATION SYSTEMS FOR RUMINANTS

3.1 Feed evaluation systems

In this chapter the feed evaluation systems of CVB for ruminants are described. Ruminants include the different categories of cattle (dairy cattle, female young stock, beef cattle), as well as sheep and goats.

For ruminants there are four feed evaluation systems established by CVB:

- A feed intake model for dairy cattle (paragraph 3.2)
- An energy evaluation system (paragraph 3.3)
- A protein evaluation system (paragraph 3.4)
- A structure value system (paragraph 3.5)

3.2 Feed intake model dairy cattle 2007

The Feed intake model 2007 is an update (developed by Wageningen UR – Livestock Research, by order of CVB) of the previous feed intake system (Zom e.a., 2002), preliminary introduced in October 2002. For more information on the Feed intake model 2007 one is referred to CVB Documentation report nr. 51 (2007) (in Dutch).
To estimate the total dry matter intake per day (TDMI) of a certain ration, the feed intake capacity (FIC) of a cow (expressed in Fill Units ("Verzadigingswaarde" in Dutch) (VW)), and the Satiety Value of the ration (VW_{diet}/kg) need to be calculated. The TDMI is then:

[F.H01] $TDMI = FIC / VW_{diet}$ (kg DM/day)

3.2.1 Feed intake capacity

To estimate the feed intake capacity of the 'standard cow' in the Feed intake model, the following equation is used:

[F.H02] $$FIC = \{[\alpha_0 + \alpha_1 \times (1 - e^{-\rho_\alpha \times a})] \times e^{\beta \times (1 - e^{-\rho_\beta \times d})}\} \times (1 + \delta_{220} \times (g/220))$$ (VW/day)

In which:

FIC	=	Feed intake capacity (VW/day)
a	=	Lactation age = parity - 1 + days in lactation/365
d	=	Days in lactation
g	=	Days in gestation
α_0	=	Initial feed intake capacity in the 1^{rst} parity (VW/day)
α_1	=	Asymptotic level (maximal increase) (VW/day)
ρ_α	=	Rate parameter for the increase of the basic curve
β	=	Maximal level adaptation with regard to the basic curve
ρ_β	=	Rate parameter for the increase of the feed intake capacity at lactation start
δ_{220}	=	Gestation parameter

From equation F.H02 it appears that the feed intake capacity, except for a number of coefficients derived from statistical analysis, depends on the following animal factors: (lactation) age (a), days in lactation (d), and the number of days that the cow is pregnant (g). These variables must be inserted for each situation to be calculated.

For $\alpha_0, \alpha_1, \rho_\alpha, \beta$ and ρ_β the following values are taken:

α_0 = 8.743 (VW/day)
α_1 = 3.563 (VW/day)
ρ_α = 1.140
β = 0.3156
ρ_β = 0.05889
δ_{220} = -0.05529

Inserting these values for $\alpha_0, \alpha_1, \rho_\alpha, \beta$ and ρ_β in equation F.H02 results in:

[F.H03] $$FIC = [8.743 + 3.563 \times (1 - e^{-1.140 \times a})] \times e^{0.3156 \times (1 - e^{-0.05889 \times d}) \times (1 - 0.05529 \times (g/220))}$$ (VW/day)

3.2.2 Correction of FIC for milk production, milk composition and body weight

While developing the 2007 version of the Feed intake model for dairy cattle, it appeared that the estimation of the feed intake could be improved for operational applications when the actual milk production, milk composition, and body weight were taken into account.

The Feed intake model that was introduced in 2002 (Zom et al, 2002) is in fact one of the modules in the so-called Cow model of Wageningen UR Livestock Research (WUR-LR). This Cow model contains, besides a prediction equation of feed intake capacity (FIC, below abbreviated as $\hat{I}c$), also equations to predict the milk production in kg per day ($\hat{M}$), the body weight in kg ($\hat{G}$), and percentages milk fat ($\hat{V}$), and milk protein ($\hat{E}$). These equations from the Feed intake model are not given in this publication, but are available from CVB.

The *realized* feed intake Ic, milk production M, the actual weight G and the percentages for milk fat V and milk protein E often deviate from the values *predicted* for the standard cow.

To correct the feed intake, as calculated with the standard equation F.H03, for the effects of the differences between realized and predicted values, the following proportional deviations have been defined:

$$ki = 100\left(\frac{Ic}{\hat{I}c} - 1\right),\ km = 100\left(\frac{M}{\hat{M}} - 1\right),\ kg = 100\left(\frac{G}{\hat{G}} - 1\right),\ kv = 100\left(\frac{V}{\hat{V}} - 1\right) \text{ en } ke = 100\left(\frac{E}{\hat{E}} - 1\right).$$

In which:

ki = the sum of all proportional corrections (in % units)
km = the proportional correction for milk production (in % units)
kg = the proportional correction for body weight (in % units)
kv = the proportional correction for milk fat content (in % units)
ke = the proportional correction for milk protein content (in % units)

It is assumed that the deviations in feed intake capacity are related to the deviations in milk production and composition, and body weight. This is reflected in the model:

[F.H04] $$ki = \beta_0 + \beta_1 km + \beta_2 kg + \beta_3 kv + \beta_4 ke + \varepsilon_{experiment} + \varepsilon_{experiment\ animal} + \varepsilon_{rest}$$

It is noted that this is not a prediction model to explain a Y variable, but a model developed to reduce the prediction error.

The corrected feed intake capacity (FIC_{corr}) is calculated according to:

[F.H05] $FIC_{corr} = (1 + ki/100) * FIC$

The values for the various k-coefficients are derived from statistical analysis: For all β coefficients, with exception of β_0, statistically significant values were obtained, when the full model, with all mentioned parameters included, was tested. The values for these β coefficients are also not given in this table, but will be made available by CVB on request.

With regard to the effect on the prediction accuracy of the feed intake capacity, it is noted that this improved with 5.2% extra explained variation when actual milk production, milk composition, and body weight were taken into account.

3.2.3 Satiety value of the diet

The satiety value of the diet is estimated by fractional adding of the satiety values of the diet components (VW_p) (f_p = fraction by which the component is included in the diet):

[F.H06] $VW_{diet} = \Sigma f_p \times VW_p$ (VW/kg DM)

Combining equations F.H3 (or F.H5) and F.H6 gives :

[F.H07] $$TDMI = \frac{FIC}{\sum_p f_p \times VW_p}$$ (kg DM /day)

In which:

TDMI	=	Total DM intake (kg DM/day)
FIC	=	Feed intake capacity (VW/day)
f_p	=	Fractional amount of the component in the diet
VW_p	=	Satiety value of the diet (VW per kg DM)

For calculating the satiety value of individual diet components, the following general model is used:

[F.H08] $$VW_p = VW_{p0} \times e^{(\lambda_{p11}(x_{p1}-\overline{x_{p1}})+\lambda_{p12}(x_{p1}-\overline{x_{p1}})^2+....+\lambda_{pn1}(x_{pn}-\overline{x_{pn}})+\lambda_{pn2}(x_{pn}-\overline{x_{pn}})^2)}$$ (VW/kg DS)

In which:

VW_p	=	Satiety value of feedstuff *p* (VW/kg DM)
VW_{p0}	=	Satiety value of feedstuff *p* at a mean composition of the feedstuff as used in animal experiments on which the VW is based (VW/kg DM)
$\lambda_{pn1}, \lambda_{pn2}$	=	Linear and quadratic satiety value parameters of feedstuff *p* for feed component *n* (n= 1, 2,…,n)
x_{np}	=	Content of feed component *n* in feedstuff *p* (g/kg DM)
$\overline{x}_{np}$	=	Mean content of feed component *n* in feedstuff *p* in the animal experiments on which the VW is based (VW/kg DM)

3.2.4 Satiety value of forages, compound feeds, and compound feedstuffs

3.2.4.1 Satiety value of forages

For a number of individual forages, a satiety value is reported on the product sheets; this satiety value is calculated using a product-specific estimation equation combined with the chemical composition of that product (also given on the product sheet). Specific estimation equations have been derived for the following forages: Corn Cob Mix (CCM), ensiled; Whole crop silage (cereals); Grass, fresh; Grass silage; Lucerne (alfalfa), fresh; Lucerne (alfalfa), ensiled; Clover,

red, fresh; Clover, red, ensiled; Maize: CCM, ensiled; Green cereals, fresh; Green cereals, ensiled; Maize (fodder maize), fresh; Maize (fodder maize), ensiled.
For the equations concerned, the reader is referred to a separate CVB publication, in which also the calculation rules for all other feed evaluation systems for ruminants are given.
For the other products given in section 9.3 'Roughages and related products' fixed values apply; these are reported on the product sheets.

3.2.4.2 Satiety value of compound feeds and compound feedstuffs

For dry concentrates (all compound feeds and compound feedstuffs) the following applies:

[F.H09] $VW_{concentrate} = 0.317 * e^{(0.001335 * (CF - 140))}$ (VW/kg DM)

3.2.4.3 Satiety value of wet feedstuffs

When deriving the satiety value of wet feedstuffs, the following (fixed) satiety values (VW/kg DM) were obtained: Beet pulp, pressed 0.70; Maize glutenfeed 0.54; Potato pulp, pressed 0.53; Brewer's grains 0.55.
Because of the minor difference between the latter three feedstuffs, it was decided to hold the following satiety values:

Product	Satiety value
Beet pulp, pressed	0.70
Maize glutenfeed	0.55
Potato pulp, pressed	0.55
Brewer's grains	0.55

For the other wet feedstuffs, also a fixed satiety value of 0.55 is assumed, with the exception of:

- Potato peelings, steamed: 0.45 (because this product contains a lot of (largely) gelatinised starch)
- High moisture industrial co-products (potato fruit-juice concentrate, potato starch, brewers' yeast, distillers solubles, cheese whey, maize solubles) and potato starch, solid: for these products a satiety value of 0.30 is assumed. This is slightly higher than calculated using the equation for dry concentrates
- For carrot peelings, steam peeled, the value for fodderbeets is taken.

3.3 Net energy systems for ruminants

For ruminants, two net energy systems are used, both based on the faecal digestibility of the Weende components:

a. The VEM-system (VEM = "Voedereenheid Melk", Feed Unit Milk) for lactating animals and young stock thereof.
b. The VEVI-system (VEVI = "Voedereenheid Vleesvee Intensief", Feed Unit Beef Cattle) for growing animals kept for beef production (with the exception of calves fed on milk replacers).

To calculate the two net energy values (VEM and VEVI value), the following aspects are important:

- The chemical composition of the feedstuff, especially the contents of crude protein, crude fat, crude fibre, and N-free extract.
- The faecal digestibility of these components.
- The general equations of the system.

3.3.1 Chemical composition of the feedstuff

Mean values for the feed components of interest for the calculation of VEM and VEVI of a feedstuff can be found on the respective product sheet. In general, chemical analysis of individual batches is recommended for a more accurate estimation of the energy value.

3.3.2 Faecal digestibility of a feedstuff

3.3.2.1 In vivo determination of the digestibility of a feedstuff for ruminants

To calculate the VEM or VEVI value of a feedstuff, the digestibility determined with wethers (castrated rams) as a model animal is used. In digestibility studies, the digestibility of crude protein, crude fat, crude fibre, and N-free extract is determined in wethers, fed on maintenance level. It is established which proportion of the ingested feed does not appear in the excreted faeces and has therefore been apparently digested. To obtain mutually comparable test results, a CVB protocol was developed for the execution of faecal digestibility studies with wethers.

3.3.2.2 Equations for the calculation of faecal digestible contents

3.3.2.2.1 Database of digestibility studies

Variation in chemical composition within feedstuffs affects the digestibility. When, for a specific feedstuff, sufficient digestibility studies with wethers are available, statistical analysis may be used to derive relationships between digestibility and chemical composition. Therefore, as many digestibility studies as possible have been collected in the CVB database.

3.3.2.2.2 Deriving equations for calculation of faecal digestible contents

For all feedstuffs where net energy values for ruminants are reported, CVB has developed equations for the calculation of the contents of the digestible components DCP, DCFAT, DCF and DNFE, required to calculate VEM and VEVI values. For most feedstuffs, these estimation equations are the result of statistical analysis (regression analysis) of datasets of digestibility studies of individual feedstuffs or combined datasets of comparable feedstuffs that may be combined in one group. For some feedstuffs, no (or not enough) digestibility studies are available to perform statistical analysis. In those cases, the digestibility was estimated by comparing the chemical composition and other characteristics of the feedstuff with other feedstuffs with known wether digestibility. When deriving estimation equations, it is continuously examined by which components the digestibility of a certain component is determined (e.g., CP digestibility is determined by the CP content of a feedstuff, but also by CF content).
When deriving equations for digestible crude protein (DCP) and digestible crude fat (DCFAT), a basal endogenous faecal excretion of 30 g CP per kg DMI and 2.5 g CFAT per kg DMI, respectively, is taken into account. For certain feedstuffs, it is not reasonable to maintain these endogenous excretions; in those cases, a value 0 (zero) is used.
On the product sheets, for each individual feedstuff, digestibility coefficients (%) are given for CP, CFAT, CF and NFE. These coefficients have been calculated by dividing the digestible content of a component (derived according to the procedure explained before) by the mean content of the component as stated on the product sheet of the feedstuff concerned; this ratio is then multiplied by 100. For feedstuff batches of which the composition differs from the mean composition on the product sheet, the digestibility coefficients on the product sheet will not be entirely correct in many cases. This applies mainly to CP and CFAT, where an endogenous excretion is taken into account. It may, however, also apply to CF and NFE, when the estimation equation also contains other parameters. The deviation of the digestibility coefficient will increase with larger deviations from the mean content of the nutrient as stated on the product sheet.
For certain chemical components and certain feedstuffs, some specific remarks - of interest for the energy value - are given below.

3.3.2.3 Products with low CFAT content

For feedstuffs with low crude fat content (≤ 15 g/kg DM) the digestibility coefficient of this component can not be established accurately in digestibility trials. For this type of products, the DCFAT is derived from the CFAT content with the following equation:

[F.H10] DCFAT (g/kg DM) = a/100 x CFAT - 2.5

in which:

a = the true digestibility of the CFAT. For most feedstuffs a=90%, except for leaf-rich plants (e.g., grass meal, lucerne meal), where a = 50%. In leaf-rich plants, a substantial part of CFAT consists of waxes and other substances that are apparently digested, but not utilized.

CFAT = the crude fat content in g/kg DM

2.5 = the above mentioned basal endogenous faecal CFAT excretion (in g/kg DMI)

3.3.2.4 Digestibility of crude fibre in products with low CF content

When the CF content of a feedstuff is low (≤ 15 g/kg DM), the digestibility coefficient of this component cannot be established accurately. The CF digestibility is kept equal to the digestibility of the NFE fraction for those low CF feedstuffs which are not part of a product group also containing feedstuffs with high CF contents, where an estimation equation for CF is derived by statistical analysis.

3.3.2.5 Animal products

Some feedstuffs of animal origin are not allowed to be fed to ruminants, due to EU-regulations. For those products, no digestibility coefficients or feeding value characteristics are reported.

3.3.2.6 Protein-rich products

For some extremely protein-rich feedstuffs, the derived content of NFE(h) is sometimes negative, because of inaccuracies in the calculation of CP from N. The reported NFE(h) digestibility of these feedstuffs is equal to the CP digestibility. The calculation of the energy value of these feeds may thus be performed in the usual manner, hence, without further corrections.

3.3.2.7 Full-fat seeds

Determining the digestibility of full-fat seeds in a digestibility trial with wethers is not easy. Because of the inhibiting action of high fat contents on cellulolytic bacteria in the rumen, only a small proportion of these seeds may be incorporated in experimental diets. Besides, the seed must undergo technological treatment to make the fat accessible for lipases; such treatment is difficult to perform on full-fat seeds. Therefore, it was decided to use the same estimation equations for the digestibility of CFAT in full-fat seeds incorporated in pelleted compound feeds (with the exception of heat treated soybeans) as for expellers and solvent extracted meals manufactured from these seeds.

3.3.3 Calculation of VEM and VEVI values

Gross and digestible contents of CP, CFAT, CF and NFE(h) are required to calculate the VEM and VEVI value. In the previous paragraphs, the chemical composition of a feedstuff and the digestibility of these components have been described.
This paragraph deals with the calculation of energy values using the general equations from the VEM and VEVI system.

The calculation of VEM and VEVI is based on the contents of metabolisable energy (ME) and gross energy (GE). The percentage ME in GE is indicated by the letter q.

3.3.3.1 Establishing GE, ME and q (general equations)

GE, ME and q are calculated as follows (Benedictus, 1977):

[F.H11] GE (kJ/kg) = 24.14 x CP + 36.57 x CFAT + 20.92 x CF + 16.99 x NFE - 0.63 x SUG*

[F.H12] ME (kJ/kg) = 15.90 x DCP + 37.66 x DCFAT + 13.81 x DCF + 14.64 x DNFE - 0.63 x SUG*
* correction for sugars (SUG) only for sugar contents > 80 g sugars per kg dry matter

[F.H13] q = 100 ME / GE

3.3.3.2 Establishing GE, ME and q (fresh and conserved forages)

The GE of forages is also calculated with equation F.H11, with the exception of maize silage. For maize silage, GE is calculated as follows:

[F.H14] GE (kJ/kg DM) = 19456 – 19.456 x ASH

For fresh and conserved forages, the calculation of ME is simplified, according to the following equation (from 2005 onwards):

[F.H15] ME (MJ/kg DM) = 14.94 DOM + 18.98 CFAT – 1.478 CF – 0.97 SUG

3.3.4 Calculation of the net energy value for milk production and of the VEM value

The net energy value for milk production (NE_{lac}) is calculated as follows:

[F.H16] NE_{lac} = 0.6 x (1 + 0.004 x (q-57)) x 0.9752 x ME (in kJ/kg)

VEM is a relative energy measure: it uses barley as a reference material. One kg of air-dried barley with a certain (standardised) composition has a mean net energy value for milk production (NE_{lac}) of 6900 kJ.

The relationship between VEM and NE_{lac} is as follows:

[F.H17] VEM = NE_{lac} / 6900 x 1000

The obtained VEM value therefore indicates how much more or less net energy a certain feed contains compared to the reference material (with a net energy of 6900 kJ per kg).

VEM may be calculated directly from ME and q as follows:

[F.H18] VEM = 0.6 x (1+0.004 x (q-57)) x 0.9752 x ME / 6.90
= (0.0003392 x q + 0.0654656) x ME

Further explanation of this equation is given below.

3.3.4.1 Efficiency for the conversion of ME into NE_{lac}

In equation [F.H18] the figure 0.6 indicates, that 60% of ME supplied above maintenance is converted to net energy (= energy in milk and growth), when a ration with q = 57 is fed. For diets

with higher q, the utilization of ME is somewhat improved, and for diets with lower q, the ME utilization is lower than 60%. This is indicated by the second part of the equation: 1 + 0.004 x (q - 57).

3.3.4.2 Correction factor for feeding level

As the digestion process is somewhat less efficient for ruminants on higher feeding levels, the ME content of a diet or feedstuff decreases with increasing feeding levels. The feeding level is expressed in units compared to maintenance requirements. When an animal consumes twice as much energy as required for maintenance (feeding level = 2x maintenance), the decrease in efficiency amounts to 1.8%. When fed at a level of 3x maintenance, the decrease is 2 x 1.8% = 3.6%, et cetera.
The above mentioned ME values are derived from experiments in which animals were fed at maintenance level. Therefore, these values need to be corrected for feeding level. It was agreed to express the VEM value of feedstuffs for feeding level 2.38. This figure has been derived from standard values for a cow of 550 kg live weight, producing 15 kg 'standard' milk (containing 4% of fat). The net energy system is based on balance experiments of which the majority was executed at (approximately) this feeding level.
At a feeding level of 2.38, a correction of -1.38 X 1.8% = -2.48% is required. This explains the third part of the VEM equation: 1 - 0.0248 = 0.9752.
For practical reasons, the influence of other feeding levels than 2.38x maintenance has been incorporated in the requirements (see CVB Table ruminants 2007 and CVB Tables Animal Nutrition 2007 or a later edition).

3.3.5 Calculating the net energy value for meat production and the VEVI value

For meat production, the net energy (in kJ/kg) (NE_{meat}) is calculated as follows:

[F.H19] $$NE_{meat} = \frac{k_f}{\frac{k_f - k_m}{APL \times k_m} + 1} \times ME$$

VEVI is a relative energy measure; it uses barley as a reference material. One kg of air-dried barley with a certain (standardized) composition has a mean net energy value for meat production (NE_{meat}) of 6900 kJ.
The relationship between VEVI and NE_{meat} is as follows:

[F.H20] $VEVI = NE_{meat} / 6900 \times 1000$

The obtained VEVI value, therefore, indicates how much more or less net energy the feed contains compared to the reference material (with a net energy of 6900 kJ per kg).
VEVI is calculated from ME and q as follows:

[F.H21] $$VEVI = \frac{k_f}{\frac{k_f - k_m}{APL \times k_m} + 1} \times \frac{ME}{6.90}$$

Correction factors are used to account for differences in utilization of ME for maintenance (k_m) and energy deposition (k_f):

[F.H22] $k_m = 0.00287 \times q + 0.554$
[F.H23] $k_f = 0.0078 \times q + 0.006$

3.3.5.1 Calculating APL

The ratio between the amount of net energy for maintenance + production and the amount of net energy for maintenance is called Animal Production Level (APL):

[F.H24] $APL = (NE_{maintenance} + NE_{production}) / NE_{maintenance}$

A growing cow weighing G kg needs 329.6 $G^{3/4}$ kJ 'net energy for maintenance':

[F.H25] $NE_{maintenance} = 329.6 \times G^{3/4}$ (in kJ)

The 'net energy for growth' for a daily weight gain of z kg is:

[F.H26] $NE_{growth} = NE_{production} = \{(500 + 6 \times G) \times z / (1 - 0.3 \times z)\} \times 4.184$ (in kJ)

At an average daily gain of 0.9 kg per day, APL is approximately 1.5; this APL is used in the calculations.

3.3.5.2 VEVI calculation: no correction of ME for feeding level

It is assumed that, with this level of production, the ME content of the diet equals the ME content at maintenance level; the error introduced by this assumption is small, since growing cattle is seldom fed at higher levels and no strong depression in digestion is to be expected.
This means that it is assumed that the feed is digested by beef cattle to the same extent as by the wethers (fed at maintenance level) used in the digestibility trials.

3.3.5.3 Correction for growth rates other than 900 g/day

The derived VEVI value is in fact only valid for a growth rate of 900 g/day. The value may also be applied to other growth rates, provided that the standards for requirements are used, which are reported for animals with growth rates as stated in paragraph 2.4 in the CVB Table ruminants 2007. In these standards, corrections have been incorporated to compensate for the error made by applying the value for a growth rate of 900 g per day to other growth rates.
Incidentally, this correction only applies to diets with a q value of around 60; for other q values, the applied correction is not fully correct.

3.3.5.4 Direct derivation of VEVI from ME for some levels of q

For some q levels VEVI can be simply derived from ME as follows:
q = 50 VEVI = 0.08054 x ME
q = 60 VEVI = 0.08939 x ME
q = 70 VEVI = 0.09728 x ME

3.3.6 Energy value of sugars, starch, organic acids and ethanol

The energy values of substances like organic acids and ethanol - mainly present in preserved feeds (forages) - cannot be established through animal experiments, since high percentages of these products are usually not accepted by the animals. By proceeding from their ATP yielding capacity, the energy value of these products may be approximated.
The maintenance metabolism of an animal is primarily driven by ATP expenditure; in production metabolism, the ATP yielding capacity plays an important role as well.
To estimate energy values through ATP yielding capacity, a certain reference substance is used, to which all products are related. The reference substance in this calculation is “100% rumen undegraded starch” (RUSTA); the ATP yield (mol) per gram of starch is known and set at 100%. The ATP production (mol) per g material of the other substances is expressed as percentage of the ATP production of the standard starch. The energy value is calculated based on this

percentage.
Example: Rumen undegraded starch yields 0.2346 mol ATP per g. Propionic acid yields 0.2432 mol/g, hence 3.7% more. Propionic acid is absorbed as such. For starch, an energy loss of 20% due to fermentation is assumed in these calculations. Proceeding from VEM and VEVI values of 1300 and 1505, respectively, the VEM and VEVI values of "100% rumen undegraded starch" are then 1625 and 1881 per kg, respectively. The VEM and VEVI values of 1 kg pure propionic acid are then 1.037 x 1625 = 1690 and 1.037 x 1881 = 1950, respectively.
As stated earlier, the net energy value of 1 kg of pure starch (the reference) is set for ruminants at 1300 VEM and 1505 VEVI, whereby it is taken into account that 20% of ATP is lost due to fermentation in the fore stomachs. For lactic acid and ethanol, an ATP loss of 10% is assumed. For glucose and saccharose an ATP loss of 30% is assumed.
For glucose, saccharose and starch, the ATP yielding capacity is the same per glucose residue. However, when glucose molecules are polymerized through glucosidic linkages, one water molecule is expelled for each molecule of glucose. Therefore, the ATP yielding capacity of a free glucose molecule is 0.90 x that of a glucose unit in a starch molecule; similarly, for saccharose, a factor of 0.95 is used.
The energy values that have been derived in this way for organic acids, ethanol, glucose and saccharose are given in the table "Other feedstuffs", which is included in the last section of Chapter 9 (paragraph 9.5) of this publication.

3.4 Protein system for ruminants

In March 2007, a revised protein evaluation system (DVE/OEB 2007) for dairy cattle has been presented, intended as an update of the DVE system that was introduced in 1991 (CVB, 1991). For the calculation of protein values, in the 2007 system more detailed equations are used than in the 1991 system; this applies to the 'system calculation rules' as well as to the 'feedstuff specific equations'. The quality of the calculations is mainly determined by the quality of the databases from *in situ* studies that underlie the product specific equations. It appears that the databases for grass silage and maize silage are of insufficient quality. Therefore, a large research project has been initiated to replace these databases by more recent ones. This is one of the reasons why the DVE/OEB 2007 system is still provisional.

3.4.1 The DVE/OEB system 1991

In 1991, the DVE system was introduced as protein evaluation system for ruminants (CVB, 1991). Per feedstuff two values are calculated:

- Intestinal digestible protein (DVE) (see paragraph 3.4.1.1)
- Rumen degraded protein balance (OEB) (see paragraph 3.4.1.2)

The DVE value represents the protein value of the feedstuff. The OEB value represents the difference between the highest possible microbial protein synthesis based on the nitrogen from rumen degraded protein on the one hand and based on available fermentable organic matter on the other hand.

3.4.1.1 Intestinal digestible protein (DVE)

Essential characteristics for calculating the DVE content are:

- The amount of protein in the feedstuff that will not be degraded in the rumen, but is digestible in the small intestine: intestinal degradable rumen undegradable protein (DRUP);
- The expected amount of intestinal digestible protein, derived from the microbial protein formed in the rumen: intestinal degradable microbial crude protein (DMCP);

- The amount of protein excreted in the faeces, derived from digestive enzymes and cells from the intestinal wall, including the amount of protein required for the biosynthesis of this endogenous protein: intestinal digestible metabolic faecal protein (DMFP):

[F.H27] DVE = DRUP + DMCP - DMFP

The amount of intestinal digestible rumen undegradable dietary protein is calculated as follows:

[F.H28] DRUP = CP * 1.11 * %RUP/100 * %DRUP/100

In intestinal flow studies (*in vivo*) it was found that %RUP was on average 11% higher compared to the value obtained in *in sacco* experiments. The factor 1.11 corrects for this difference.

3.4.1.1.1 Calculation of rumen undegraded protein (%RUP)

The protein 'undegradability' (%RUP) is estimated by incubating small amounts of a feedstuff in nylon bags in the rumen. In this method, the washable protein fraction and the protein fraction not degradable by rumen microbes are determined, as well as the rate of degradation of the potentially degradable fraction. From these data the undegradability can be estimated, assuming a certain rate of passage:

[F.H29] $\%RUP = U + k_p/(k_d+k_p) * D$
(this equation does not apply to ensiled or fermented wet feedstuffs, see next paragraph)

[F.H30] D (%) = 100 – U - W

In which:

U	=	undegradable protein fraction (undigestible) (%)
D	=	potentially degradable protein fraction (digestible) (%)
W	=	washable protein fraction (%)
k_p	=	passage rate of protein from the rumen (% per hour)
k_d	=	degradation rate of protein in the rumen (% per hour)

3.4.1.1.2 Calculation of %RUP for fermented feedstuffs

For ensiled feedstuffs and for high moisture industrial co-products that have been fermented at the time of delivery and feeding (even though they may be called 'fresh'), the washable fraction partly consists of microbial protein formed in this fermentation process. This protein moves along with the liquid phase and will therefore partly escape from rumen degradation. For such products it is assumed that 5% of the washable fraction escapes from rumen degradation. The equation to calculate %RUP for these feedstuffs therefore is as follows:

[F.H31] $\%RUP = U + k_p/(k_d+k_p) * D + 0.05*W$

3.4.1.1.3 Passage rate of feedstuffs

Many uncertainties exist with respect to the passage rate and variation therein. Estimations vary from 3 to 8% per hour. For the feedstuffs contained in this Feed Table a passage rate of 6% per hour is assumed. For 'roughages' (products with a minimum structural value of 1.2 and a mean particle size of at least 8 mm) a passage rate of 4.5% is assumed.

3.4.1.1.4 Origin of data concerning rumen bypass protein

To derive the values reported in this Feed Table, experimental data from nylon bags incubations obtained at the IVVO-DLO research institute (now Wageningen UR – Livestock Research) were used. The results from these experiments were compared to literature data from the Netherlands

and other countries. The level of the outcomes often differed, but the ranking of feedstuffs was in most cases the same as found by IVVO-DLO. Therefore, the results per research institute were calculated back to the Dutch (IVVO-DLO) level, using linear regression. Subsequently, the mean values per feedstuff were calculated (Van Straalen and Tamminga, 1990). For feedstuffs for which no information was available, an estimated value was calculated with the use of comparable feedstuffs.

3.4.1.1.5 Intestinal digestibility of the undegraded protein (%DRUP)

The intestinal digestibility of the undegraded protein (%DRUP) is, in general, derived from measurements using the so-called mobile nylon bags method: A small amount of feedstuff is incubated in the rumen for 12 to 18 hours. Thereafter, the sample is placed in a nylon bag and entered in the small intestine. After passage through the intestinal tract the nylon bag is recovered from the faeces. The amount of N that is lost during the passage through the intestinal tract is assumed to be digested.

3.4.1.1.6 Origin of data concerning %DRUP

The %DRUP values given in the tables were derived from research by the IVVO-DLO research institute (now Wageningen UR – Livestock Research) and from literature data (Van Straalen and Tamminga, 1990). The %DRUP values for forages and some wet feedstuffs have provisionally been calculated from the undegradability and the fraction that is not degraded after prolonged incubation in the rumen (Tamminga and Ketelaar, 1988). When information was missing, %DRUP was estimated from available %DRUP values of similar feedstuffs; for cell wall rich crop residues – like husks/shells – a low %DRUP (50%) was assumed. For feedstuffs of which no data for comparable products were available, the intestinal digestibility is - for now - estimated to be 75%.

3.4.1.1.7 Amount of intestinal digestible microbial protein (DMCP)

The amount of intestinal digestible microbial protein is calculated as follows:

[F.H32] DMCP = 0.0956 * FOM
= 0.0956 * (DOM – CFAT – (CP * %RUP/100) – (STA * %RUSTA/100) – 0.50 * FP)

The rumen fermentable organic matter (FOM) is calculated by subtracting all components that do not supply energy to the micro-organisms in the rumen from DOM. These components are:

- Crude fat (CFAT)
- Rumen undegradable protein (CP * %RUP/100)
- Rumen undegradable starch (STA + %RUSTA/100)
- 50% of the fermentation products (FP = acetic acid + propionic acid + butyric acid + lactic acid + ethanol)

In some cases, where FOM becomes negative, FOM is set to 0 (zero). The DOM (= digestible organic matter) equals the (apparently) digestible crude protein + digestible crude fat + digestible crude fibre + digestible N-free extract.

In the calculation of DMCP it is assumed that 150 g microbial protein (N*6.25) may be formed per kg of fermentable organic matter, that 75% of this microbial protein consists of amino acids, and that 85% of these amino acids is digestible in the small intestine.

Therefore, DMCP may be calculated from FOM using the following factor:

0.150 * 0.75 * 0.85 = 0.0956

In the calculation of the fermentable organic matter of some feedstuffs, a correction has been included for fermentation products that are formed during treatment (e.g., ensiling). The energy value of some fermentation products (lactic acid, ethanol) is 50% of the energy value of

carbohydrates. Therefore, for fermented feedstuffs, 50% of the FP is subtracted from DOM. The data used in this Table were collected by Steg et al. (1990).

3.4.1.1.8 Amount of intestinal degradable microbial crude protein (DMCP)

The amount of intestinal digestible microbial protein is calculated with the equation:

[F.H33] DMCP = 0.075 x iDM = 0.075 * (DM – DOM – DASH)

The inevitable faecal protein losses are assumed to depend on the undegraded dry matter intake (iDM). The undegraded dry matter intake may be calculated from the amount of dry matter minus the amount of digestible organic matter (DOM) and the amount of digestible crude ash (DASH).
The digestibility of crude ash (%DASH) is, depending on the feedstuff, set to 35, 50 or 65. These values were - for each feedstuff - derived from the amounts of Na, K, Cl, Ca, Mg and P in the crude ash. It is further assumed that the digestibility of Na, K and Cl is 100%, and the digestibility of Ca, Mg and P is 50%.
For the calculation method the reader is referred to CVB series nr 7 (1991). The DASH value in equation [F.H33] is calculated as follows:

[F.H34] DASH = %DASH/100 * ASH

This equation may be used provided that the resulting DASH value does not exceed the MDASH value in the CVB Feed Table. In other cases, the MDASH value should be used in the calculation. MDASH is calculated as follows:

[F.H35] MDASH = %DASH/100 * (1.1 * ASH_{table} + 10)

In which ASH_{table} is the crude ash content as given on the product sheet.
Added minerals are supposed to be 50% digestible, without upper limit. Table salt is probably 100% digestible.
The metabolic faecal protein losses are calculated under the assumption that 75 gram of DMCP is lost per kg iDM.

3.4.1.2 The rumen degraded protein balance (OEB)

The rumen undegraded protein balance (in Dutch: Onbestendig Eiwit Balans, OEB) represents the difference – on rumen level – between the maximum potential microbial protein synthesis, based on the available amount of degradable protein on the one hand, and the maximum potential microbial protein synthesis, based on available energy on the other hand. The OEB value of the ration should never be negative (except for beef cattle and youngstock weighing at least 250 kg and provided with above standard DVE supply; for more information see the most recent version of the CVB Tables Animal Nutrition). With a negative OEB value, there is not enough nitrogen available in the rumen to attain the calculated DMCP:

[F.H36] OEB = {CP * (1 – 1.1 * %RUP/100)} – (FOM * 0.150}

3.4.1.3 Intestinal digestible amino acids

In 1998, the CVB Working Group Nutrition Ruminants and Horses established a procedure to calculate the contents of intestinal digestible methionine and lysine (DVMET and DVLYS, respectively) (CVB, 1998a). This report describes the various relevant aspects of a uniform calculation procedure for obtaining DVMET and DVLYS in feedstuffs for ruminants. The calculation is performed according to the calculation rules in the DVE system.
For the contribution of dietary protein to DVMET and DVLYS, the following remarks apply:

- The undegradability of these amino acids from compound feedstuffs appeared to be not significantly different from the undegradability of N or crude protein (CP). For forages, this may be different, but insufficient data are available to suggest another calculation procedure.

- The intestinal digestibility of methionine in rumen incubation residues after 12 to 18 hours of rumen incubation appeared to be – slightly but significantly – higher than the CP digestibility in these residues. For lysine, this was not the case.

To be able to calculate the contribution from microbial protein to the content of intestinal digestible methionine and lysine, an amino acid pattern of microbial protein had to be established. After a literature study of published amino acid patterns, CVB composed its own extended database. Based on this database, the content of methionine and lysine in microbial protein was set to 2.5 and 7.7 g/100 g AA, respectively.

To account for the methionine and lysine losses in DMCP, a pattern was chosen that was calculated from the endogenous excretion as determined in sheep by Van Bruchem et al. (1985). This implies that the methionine and lysine content in DMCP is assumed to be 1.5 and 5.7 g/100 g AA, respectively.

The equations for calculating the content of intestinal digestible methionine (DVMET) then become:

[F.H37] DVMET = DRUMET + DMMET – DMFMET
[F.H38] DRUMET = MET/100 * DRUP/0.96
[F.H39] DMMET = 0.025 * DMP
[F.H40] DMFMET = 0.015 * DMFP

In which:
DRUMET = methionine contribution from intestinal digestible rumen undegraded dietary protein (=DRUP)
DMMET = methionine contribution from intestinal digestible microbial protein (=DMP)
DMFMET = methionine contribution from intestinal digestible metabolic faecal protein (=DMFP)
MET = methionine content in the feedstuff (in g per 16 g N = in g per 100 g CP)

For the calculation of the intestinal digestible lysine content (DVLYS) the following equations apply:

[F.H41] DVLYS = DRULYS + DMLYS – DMFLYS
[F.H42] DRULYS = LYS/100 * DRUP/0.96
[F.H43] DMLYS = 0.077 * DMP
[F.H44] DMFLYS = 0.057 * DMFP

In which:
DRULYS = lysine contribution from intestinal digestible rumen undegraded dietary protein (=DRUP)
DMLYS = lysine contribution from intestinal digestible microbial protein (=DMP)
DMFLYS = lysine contribution from intestinal digestible metabolic faecal protein (=DMFP)
LYS = lysine content in the feedstuff (in g per 16 g N = in g per 100 g CP)

DRUP, DMP and DMFP are calculated according to the calculation rules within the DVE system.

3.4.1.4 Rumen undegraded starch (%RUSTA)

The resistance of starch against degradation in the rumen (%RUSTA) is derived from nylon bags experiments (Tamminga et al., 1989).
The differences found between *in vivo* and *in vitro* measurements call for a correction: it is assumed that 10% of the washable fraction escapes from degradation in the rumen.This washable fraction leaves the bags in the form of small starch granules and these granules are flushed out of the rumen with the liquid phase, or are stored in micro-organisms.
The method of determination also plays a role in starch validation for cattle, as for pigs. It is known that the Ewers method gives an overestimation of the true starch content of some products, like, e.g., soy products. For these types of products a method with amyloglucosidase

(ISO/DIS 15814) yields better results. In cases where the Ewers method results in artefacts, this method should in fact not be used. In *in situ* experiments, an amyloglucosidase method is always used for starch analysis.
In cases where experimental information on starch undegradability is lacking, the rumen undegraded starch was estimated, mostly by comparison with similar feedstuffs. When this was also not feasible, %RUSTA was set at a low level, namely 10%.
Products for which the Ewers method (strongly) overestimates the true starch content are usually products with (extremely) low true starch content. Therefore, data from *in situ* incubations are also lacking. For such products, %RUSTA is set to 0 (zero) in the CVB Feed Table.
The %RUSTA values obtained for compound feedstuffs were multiplied by 0.875 to account for the effect of pelleting on starch undegradability.
In feedstuffs that underwent high temperature and pressure treatment (e.g., extrusion, expansion and pressure cooking), starch will be hydrolysed and %RUSTA will be very low. It is assumed that starch in such products is for 95% degradable in the rumen. %RUSTA is therefore set to 5%.
In cases where %RUSTA is not based on *in situ* incubations in nylon bags, but is estimated, %RUSTA is - after correction for pelleting - rounded to a multiple of five.
On the product sheets, %RUSTA is given, including the correction for pelleting.

3.4.1.5 Rules for the calculation of rumen undegraded protein (%RUP)
From the CVB Feed Table 2000 onwards, an equation for the calculation of rumen undegraded protein based on chemical composition was included for the product potato pulp.
For potato pulp (4001.226/0):

[F.H45] %RUP = 5569 * 1/[CP * (1000/(1000-STAam)) * (1000/(1000-ASH))]

In which:
%RUP as percentage
ASH, CP and STAam in g/kg DM

3.4.1.6 Reported values DVE/OEB system 1991 on product sheets
On the product sheets, for each individual feedstuff, the following values are given: %RUP, %DRUP, %RUSTA, %DASH, MDASH (in g per kg product or DM), and (in g per kg product or DM): FOM, DVE, OEB, DVLYS and DVMET.

3.4.2 The (provisional) DVE/OEB 2007 system
In March 2007 an updated protein evaluation system for dairy cattle (DVE/OEB 2007 system) was presented, to succeed the DVE system that was introduced in 1991 (CVB, 1991). Detailed information concerning the system is given in CVB Documentation report no 52 (CVB, 2007).
For each feedstuff, six values are calculated:

- Intestinal digestible protein (in Dutch: darmverteerbaar eiwit, DVE)
- Rumen degraded protein balance (in Dutch: onbestendig eiwit balans, OEB)
- Fermentable organic matter in the rumen (FOMr, see paragraph 3.4.2.3)
- Rumen degraded protein balance two hours after feed intake (OEB-2, see paragraph 3.4.2.2)
- Fermentable organic matter in the rumen two hours after feed intake (FOMr-2, see paragraph 3.4.2.3)
- The ratio between FOMr-2 and FOMr (FOMr-2/FOMr, see paragraph 3.4.2.3)

The DVE value represents the protein value of the feedstuff and was also included in the DVE/OEB system 1991. The same applies to the OEB value that represents the difference between the maximum potential microbial protein synthesis based on nitrogen from degraded protein on the one hand and the maximum potential microbial protein synthesis based on available fermentable organic matter on the other hand. However, both characteristics are calculated differently: FOMr is the amount of organic matter from a feedstuff that is fermented in

the rumen and FOMr is calculated in a fundamentally different manner than FOM in the DVE/OEB 1991 system. The other three parameters were not included in the DVE/OEB 1991 system and provide insight in the dynamics and rate of fermentation in the rumen.

3.4.2.1 Intestinal digestible protein (DVE)

DVE in the DVE/OEB 2007 system consists of the same components as DVE in the DVE/OEB 1991 system:

- The amount of protein in the feedstuff that will not be degraded in the rumen, but is digestible in the small intestine: intestinal degradable rumen undegraded protein (DRUP)
- The amount of intestinal digestible protein from microbial protein that is produced in the rumen: intestinal degradable microbial protein (DMP)
- The amount of protein excreted with the faeces deriving from digestive enzymes and gut wall cells, including the amount of protein required to synthesize this endogenous protein: intestinal degradable metabolic faecal protein (DMFP)

[F.H45] DVE = DRUP + DMP – DMFP

3.4.2.1.1 Intestinal degradable rumen undegraded protein (DRUP)

The amount of intestinal degradable rumen undegraded feed protein is calculated in the DVE/OEB 2007 system as follows:

[F.H47] DRUP = CP * %RUP/100 * %DRUP/100 [a]

In which:
CP = crude protein (g/kg or g/kg DM)
%RUP = rumen undegradability of the protein (in %)
%DRUP = intestinal digestibility of the undegraded protein (in %)

This calculation slightly differs from the procedure in the DVE/OEB 1991 system (see [F.H28] in paragraph 3.4.1.1.1; the correction factor 1.11 is dropped).

3.4.2.1.2 Calculation of rumen undegradability of protein (%RUP)

The undegradability of protein in the rumen (%RUP) is estimated from the results of nylon bag incubations. Small amounts of a feedstuff are incubated in nylon bags in the rumen. In the residues after various incubation periods the remaining amount of nutrients is determined. A distinction is made between a washable (W) fraction that is washed out of the bags without rumen incubation, an undegradable (U) fraction, and a (calculated) potentially degradable fraction (D). The rate of degradation of the D fraction (k_d) is also determined. In the DVE/OEB 2007 system, the W fraction is divided into a soluble fraction (S, determined at the laboratory) and a remaining fraction consisting of small particles (W-S). The undegradability of compound feedstuffs and wet feedstuffs may be calculated from these data, according to the following equation:

[F.H48] $\%RUP = 11/(200+11)*S + 8/(8+k_{dD})*(W-S) + 6/(6+k_{dD})*D + U$

In which:
S = soluble CP fraction (%)
(W-S) = CP in the small particles fraction
W = washable CP fraction (%)

a For forages and high moisture industrial co-products 'CP´ should be replaced by ´CP_{in}´, the CP content including ammonia. In the DVE calculation of high moisture industrial co-products it is assumed that the ammonia fraction = 0 (and, therefore, that CP = CP_{in}), although (especially after ensilation) a small amount of ammonia is present.

D = potentially degradable CP fraction (%) (D = 100 – W – U)
U = undegradable CP fraction (%)
11 = passage rate from the rumen of the S fraction (% per hour)
8 = passage rate from the rumen of the (W-S) fraction (% per hour)
6 = passage rate from the rumen of the D fraction (% per hour)
200 = rate of CP degradation of the S fraction in the rumen (% per hour)
k_{dD} = rate of CP degradation of the D and the (W-S) fraction in the rumen (% per hour)

For forages the following equation applies:

[F.H49] %RUP = $11/(200+11)*S + 8/(8+k_{dD})*(W-S) + 4.5/(4.5+k_{dD})*D + U$

The only difference being the passage rate of the D fraction; for forages, this passage rate is assumed to be 4.5% per hour. For bulbs and tubulars, this rate is 6% per hour.

3.4.2.1.3 Origin of data concerning protein undegradability (%RUP)

The *in situ* data that underlie the protein values in this table are - with respect to protein undegradability - derived from a CVB dataset, mainly based on nylon bag studies executed by Wageningen UR – Livestock Research in Lelystad. The data have been supplemented by research which was done in 2004 by order of the Product Board Animal Feed on behalf of CVB. Some data from Dutch and foreign literature have also been included.

3.4.2.1.4 Intestinal digestibility of the undegraded protein (%DRUP)

The reference method for determining the intestinal digestibility of undegraded protein (%DRUP) concerns the measuring of the disappearance of the protein from nylon bags using the so-called mobile nylon bags method. In this technique, a small amount of feedstuff is, after 12 to 18 hours of rumen incubation, transferred in a nylon bag at the beginning of the small intestine. After passing through the digestive tract, the bag is collected from the faeces. The amount of N that disappeared during passage is assumed to be digested.
Although the mobile nylon bags method is the reference method, such data are not available for all feedstuffs. In those cases, the %DRUP value is based on nylon bags trials in the rumen. The %DRUP is based on the fraction that is not digested after prolonged rumen incubation.
When information was lacking, values were estimated from similar feedstuffs, if possible. Plant residues rich in cell walls (e.g., husks) were estimated low (50%). When no data on similar feedstuffs were available, the intestinal digestibility was estimated, for the time being, to be 75%.

3.4.2.1.5 Intestinal degradable microbial crude protein (DMP)

The amount of intestinal digestible microbial protein is calculated from the amount of microbial crude protein produced based on rumen available energy (MCPe), according to the same equation as in the DVE/OEB 1991 system:

[F.H50] DMP = 0.75 * 0.85 * MCPe

In which:
0.75 = the amount of true protein in MCPe
0.85 = the intestinal digestibility of the true protein
MCPe = microbial crude protein produced based on the in the rumen available energy (g/kg or g/kg DM)

The calculation of the amount of MCPe in the DVE/OEB 2007 system, however, differs completely from the calculation in the DVE/OEB 1991 system. The amount of MCPe produced in the rumen during fermentation of a feedstuff depends on:

- The type of substrate that is fermented:
  Certain substrates yield much more ATP per gram than others.

- The type of bacteria that ferment the substrate:
  A distinction is made between LAB (= Liquid Associated Bacteria) and PAB (= Particle Associated Bacteria). The S and (W-S) fractions are fermented by LAB; the D fraction by PAB.
- The amount of ATP available for the production of bacterial mass:
  This is the amount of ATP that is released with the fermentation of a certain substrate minus the amount of ATP required for 'bacterial maintenance processes'. This is determined by - on the one hand - the maintenance requirements of the bacteria, and - on the other hand - by the residence time of the bacteria in the rumen (the reciprocal of the passage rate). The maintenance requirement of LAB, expressed as mmol ATP per gram of bacteria per hour, is much higher than the maintenance requirement of PAB. On the other hand, the residence time of PAB in the rumen is much longer than the residence time of LAB, so that PAB use ATP for maintenance for a longer period of time than LAB.
- The proportion of CP per kg of bacterial mass;
- The preying upon bacteria by protozoa.

The following equation is used to calculate the amount of MCPe from an average forage:

[F.H51] $MCPe = 0.174*F_{S}SUG + 0.166*F_{(W-S)}STA + 0.253*F_{D}STA + \underline{0.138}*F_{D}NDF + 0.145*F_{(W-S)}RNSP + \underline{0.168}*F_{D}RNSP + 0.099*F_{S}CP + 0.082*F_{(W-S)}CP + 0.110*F_{D}CP + 0.087*F_{S}FP$

In which:

F = the rumen fermented fraction of a certain feed component (SUG, STA, NDF, RNSP, CP, FP), whereby the subscripts ($_{S,\ (W-S),\ D}$) refer to the fraction in the nylon bag procedure.

0.174 = the efficiency factor for the utilization of energy from $F_{S}SUG$ to produce MCPe (similar for all other coefficients)

<u>0.138</u> = this efficiency factor applies to a D-NDF fraction with a mean degradation rate. The kp of D-NDF depends on the kd of this fraction; the efficiency factor of $F_{D}NDF$ therefore depends on the kd. The same applies to the efficiency factor of the $F_{D}RNSP$ (where the efficiency factor of 0.168 refers to a D-RNSP fraction with a mean degradation rate).

<u>Please note</u>: For products containing GOS, the GOS fraction should be included in the calculations in the same manner as the SUG fraction.

The equation for calculating MCPe from a compound feedstuff or a wet feedstuff is similar to F.H51, except for the efficiency coefficients for $F_{D}NDF$ and $F_{D}RNSP$: mean values of 0.168 and 0.175, respectively, are assumed. Further, for the $F_{D}CP$ fraction a coefficient for concentrates of 0.126 is used and 0.110 for roughages.
It is noted that the amount of MCPe, calculated according to [F.H51], will be produced only when OEB is not negative.

3.4.2.1.6 Amount of intestinal degradable metabolic faecal protein (DMFP)

The calculation of the amount of intestinal digestible metabolic faecal protein (DMFP) in the DVE/OEB 2007 system is exactly the same as in the 1991 system. The amount of DMFP is calculated as follows:

[F.H52] DMFP = 0.075 x iDMI = 0.075 x (DM - DOM - DASH)

The inevitable faecal protein losses are supposed to depend on the indigestible dry matter intake (iDMI). The indigestible dry matter intake may be calculated from the amount of dry matter (DM) minus the amounts of digestible organic matter (DOM) and digestible crude ash (DASH).
The digestibility of the crude ash (%dASH) is, depending on the feedstuff, set on 35, 50 or 65. These values were derived per feedstuff from the contents of Na, K, Cl, Ca, Mg and P present in

ASH. It is further assumed that the digestibility of Na, K and Cl is 100%, and that the digestibility of Ca, Mg and P is 50 %.
More information on the calculation method is given in CVB series nr. 7 (1991).
The DASH value in F.H52 is calculated according to:

[F.H53] DASH = %dASH/100 x ASH

This equation may only be used if the resulting DASH value does not exceed the MDASH value form the Feedstuff Table. If the DASH value is higher, one should use the MDASH value, which is calculated as follows:

[F.H54] MDASH = %dASH/100 x (1.1 x ASH_{table} + 10)

in which ASH_{table} is the ASH content on the product sheet.
Added minerals are supposed to be 50% digestible, with no maximum value. For NaCl (table salt) 100% digestibility is likely.

The metabolic faecal protein losses are calculated under the assumption that 75 g DMFP is lost per kg of DM.

3.4.2.2 The rumen degraded protein balance (OEB)

The rumen degraded protein balance (in Dutch: Onbestendig Eiwit Balans, OEB) represents the difference (at rumen level) between the maximum possible microbial protein synthesis, based on the available amount of degradable protein on the one hand, and the maximum possible microbial protein synthesis, based on the available amount of energy on the other. The OEB value of the ration may (with the exception of beef cattle and young stock from 250 kg LW, and a DVE supply above the standard; see the most recent version of the CVB Feed Table) never be negative, because in that case not enough N is available in the rumen to reach the calculated DMP:

[F.H55] OEB = MCPn – MCPe

In which:
MCPn = the maximum possible microbial protein synthesis based on available nitrogen (= CP x (1 - %RUP/100)
MCPe = the maximum possible microbial protein synthesis based on available energy (the calculation of MCPe is explained in F.H51, paragraph 3.4.2.1.5).

The new protein system also offers the opportunity to check the supply of N and energy at the rumen level in the short term. Therefore, the OEB-2 is also reported as a parameter, in addition to OEB as such.

3.4.2.3 Fermentable organic matter in the rumen (FOMr)

In paragraph 3.4.2.1.5, all fractions of rumen fermented organic matter are stated in [F.H51]. When these values are added up, the total amount of rumen fermentable organic matter is obtained (FOMr).
To gain insight in the degradation rate of organic matter in the rumen, the amount of FOMr that is fermented during the first two hours after intake can be calculated (= FOMr2). A more comprehensible parameter is the ratio FOMr2/FOMr. For each product, FOMr2 and FOMr2/FOMr are reported besides FOMr.

3.4.2.4 Intestinal digestible amino acids

The supply of intestinal digestible amino acids is calculated in the DVE/OEB 2007 system according to the rules described in CVB Documentation report nr. 22, in Dutch (CVB, 1998a).

The equations for calculating the content of intestinal digestible methionine (DVMET) are as follows:

[F.H56] DVMET = DRUMET + DMMET – DMFMET
[F.H57] DRUMET = MET/100 x DRUP / 0.96
[F.H58] DMMET = 0.025 x DMP
[F.H59] DMFMET = 0.015 x DMFP

In which:
DRUMET = methionine contribution from DRUP (= Digestible Rumen Undegradable Protein)
DMMET = methionine contribution from DMP (= Digestible Microbial Protein)
DMFMET = methionine contribution from DMFP (= Digestible Microbial Faecal Protein)
MET = methionine content in the feedstuff (in g/16 g N, or in g/100 g CP)

To calculate the content of intestinal digestible lysine (DVLYS), the following equations apply:
[F.H60] DVLYS = DRULYS + DMLYS - DMFLYS
[F.H61] DRULYS = LYS/100 x DRUP
[F.H62] DMLYS = 0.077 x DMP
[F.H63] DMFLYS = 0.057 x DMFP

in which:
DRULYS = lysin contribution from DRUP (= Digestible Rumen Undegradable Protein)
DMLYS = lysin contribution from DMP (= Digestible Microbial Protein)
DMFLYS = lysin contribution from DMFP (= Digestible Microbial Fecal Protein)
LYS = lysin content in the feedstuff (in g/16 g N, or in g/100 g CP)

Calculation of DRUP, DMCP and DMFP is done in conformity with the rules of the DVE system.

3.4.2.5 Sugars, glucose oligosaccharides (GOS) and crude fat in the DVE/OEB 2007 system

In the DVE/OEB 2007 system it is assumed that all sugars and GOS that are present in feedstuffs will end up in the S fraction. This implies that 95% is degraded in the rumen, and 5% escapes rumen degradation through passage from the rumen.
Crude fat is required in the new system to calculate the degradation characteristics of RNSP. The following rules apply: W = 35%; U = 0; Kd_D = 15% per hour. Note: in this case Kd_D is not the degradation rate (CFAT is not fermented in the rumen), but the “rate of disappearance”.

3.4.2.6 Rumen undegraded starch (%RUSTA)

In the DVE/OEB 2007 system, for the degradation of starch a distinction is made between the small particles fraction (W-S) and the D fraction. This distinction was not made in the DVE/OEB 1991 system. The fraction soluble starch (S) is zero or negligible. Therefore (W-S) = W. The degradation rate of the W-S fraction is calculated by:

[F.H64] $kd_W = 2*kd_D + 0.375$.

The kp of the D fraction of starch is for all feedstuffs (including forages) set at 6% per hour.
When compound feeds are (heat) pelleted, the undegradability of starch decreases. In the DVE/OEB 2007 system, the effect of pelleting is taken into account by assuming a decrease of the D fraction, because pelleting is supposed to mainly damage the structure of the particles in the D fraction:
D’ = 0.75 * D and W’ = 100 - D’ (in which D’ = D fraction after pelleting).
For feedstuffs in which the starch is hydrolyzed by heat- or pressure-treatment (e.g., extrusion, expansion, pressure cooking), the %RUSTA will be very low. For products with hydrolyzed

starch, 95% of the starch is supposed to be degraded in the rumen. The %RUSTA is therefore set at 5%.
Feed ingredients for which %RUSTA is not based on *in situ* incubations in nylon bags in the rumen, but on estimations, %RUSTA is (after applying the correction for pelleting) rounded off to a multiple of five. On the product sheets, %RUSTA is given including the correction for pelleting.

3.4.2.7 Degradation characteristics of NDF and RNSP

For NDF, in the DVE/OEB 2007 system a D and a U fraction are distinguished. The W fraction is set to zero.
To determine the degradation curves of RNSP in nylon bags experiments, this fraction should be calculated for each incubation time, by subtracting the still present amounts of CP, CFAT and NDF from the still present amount of OM. Because of the composition of the RNSP fraction, it is likely that this also contains a W fraction, which will partly consist of an S fraction. The latter cannot be quantified, however, it's existence justifies a higher degradation rate for the W fraction of RNSP than for the D fraction:

[F.H65] kd_W-RNSP = 2.5 * kd_D-RNSP

The passage rate (kp) of the D fraction of NDF and RNSP is calculated from the relationship between kp and kd:

[F.H66] For forages: kp_D (% per hour) = 1.39 + 0.1775*kd_D
[F.H67] For concentrates: kp_D (% per hour) = 1.885 + 0.1775*kd_D

With kd_D in % per hour.

3.4.2.8 Statement of DVE/OEB 2007 system values on product sheets

The equations to estimate the various degradable fractions per chemical parameter and per feedstuff are not provided in this document.
On the product sheets, the following values are given: %RUP, %DRUP, %MDASH, MDASH (in g per kg product or g per kg DM), and (in g per kg product or in g per kg DM): FOMr, FOMr2, OEB, OEB-2, DVLYS and DVMET, and the ratio FOMr2/FOMr.

3.5 Structure value (SV)

Rumen acidosis caused by fast rumen fermenation of carbohydrates should be prevented. This can be achieved by setting limits to the 'structure value' (SV) of a ration within a structure value system. Since 1998, the CVB tables make use of the structure value system developed by the "Rijksstation voor de Veevoeding" (at present "Unit Animal" of the "Instituut voor Landbouw- en Visserijonderzoek (ILVO)" in Melle-Gontrode (Belgium) (for more information on this system and the standards, see CVB Documentation report nr. 23 (CVB, 1998b)). In 2002, the Unit Animal of ILVO has implemented some minor adaptations in the equations to calculate SV and in the requirement standards. These adaptations have been incorporated in this table.
In the structure value system, for calculating the structure value of compound feedstuffs, two equations are available: one based on CF and one based on NDF. For many feedstuffs in the Animal Feed Table, the NDF content is based on a limited amount of data. For a number of feedstuffs, CVB developed relations between NDF and CF to estimate the NDF content. Depending on the number of data underlying the NDF content on the product sheet, the former CVB working group Animal Feed Table decided to base calculation of the SV on either an estimation equation with the NDF content, or an equation with the CF content. Because of the relative importance of dry compound feedstuffs, compound feeds and wet feedstuffs for the SV of

the complete ration, it was also decided to use (from 2003 onwards) STAam for the required starch content.
For compound feedstuffs, the SV is, therefore, calculated according to one of the following equations:

[F.H68] SV (per kg DM) = 0.321 + 0.00098*CF + 0.00025*RUSTA – 0.00112*(SUG + a*FSTA)

[F.H69] SV (per kg DM) = 0.175 + 0.00082*NDF + 0.00047*RUSTA – 0.00100*(SUG + a*STA)

In which:
a = 0.9 – 1.3*(%RUSTA/100)
FSTA = fermentable starch (=STA – RUSTA)
STA = STAam
RUSTA = STAam * %RUSTA/100
All contents in g per kg DM

> For the following feedstuffs the SV is calculated according to equation [F.H69]: malt culms; soybeans, heat treated; soybean hulls; soybean expeller; soybean meal, rumen bypass; sorghum; tapioca; tapioca starch.
> For all other products, SV is calculated according to equation [F.H68]

The structure values of compound feedstuffs apply to materials in milled form, processed into pellets.

A number of feedstuffs that consist largely of only one Weende component, like oils, fats and limestone has been assigned a SV of 0.15.
The derived SV for the most relevant wet feedstuffs are given in Table 3.2

Table 3.2 Structure value of most relevant moisture rich industrial co-products for ruminants (SV per kg DM)

Product group	Feedstuff	SV
Corn Cob Mix, as such or ensiled	Corn Cob mix, ensiled	0.75
	CCM, 100% rachis	0.60
	CCM, 50% rachis	0.50
	CCM, 25% rachis	0.40
Byproducts	Potato pulp, pressed	0.80
	Potato cuttings/chips	0.60
	Brewer's grains, ensiled	1.00
	Beet pulp, ensiled	1.05
	Maize glutenfeed, fresh or ensiled	0.60

For the criteria for the structure value of a ration, the reader is referred to CVB Documentation report No 23 (CVB, 1998b), or to the most recent version of the CVB Feed Table.

3.6 Calculation examples

Document RD006 on the CVB-website www.cvbdiervoeding.nl gives a step-by-step explanation of the calculation of feeding values for ruminants within the various systems.

4. FEED EVALUATION SYSTEMS FOR PIGS

4.1 Feed evaluation systems

In this Chapter the feed evaluation systems of CVB for pigs are explained. For pigs, three feed evaluation systems have been established by CVB:

- A net energy system (paragraph 4.2)
- A protein / amino acids system (paragraph 4.3)
- A digestible phosphorus system (paragraph 4.4)

4.2 Net energy system

For the determination of the net energy value for pigs the following aspects are of importance:

- The chemical composition of the feedstuff,
- The faecal digestibility of crude protein, crude fat, and non-starch polysaccharides (NSP).
- The ileal digestibility of starch and the digestibility (enzymatical and fermentative) of sugars,
- The general equations for the calculation of net energy according to this system.

4.2.1 Chemical composition of the feedstuff

Mean values for the feed components of interest in the calculation of the net energy value of a feedstuff can be found on the appropriate product sheets. In general, it is advised to chemically analyze individual batches of feedstuffs for a more accurate estimation of the energy value of that batch.

4.2.2 Digestibility values

4.2.2.1 Determination of the in vivo digestibility of feedstuffs for growing pigs

The faecal digestibility coefficients for crude protein, crude fat, and NSP have been derived from digestibility trials with growing pigs. In these trials it is determined which part of an ingested feed component does not appear in faecal matter and is therefore apparently digested. In this edition of the Feed Table for a substantial number of feedstuffs (and for almost all feedstuffs that are regularly fed to pigs) the digestibility values have been updated based on recently carried out digestibility trials. These trials were carried out according to CVB protocol for growing pigs (2005) using pigs in the weight range of 40 tot 100 kg and using a feed level of around 820 kJ net energy (NE) per kg of metabolic weight ($BW^{3/4}$). This is a feed level of around 2.8 – 2.9 times the maintenance energy requirement. At this feeding level it is expected that the determined digestibility values do not substantially deviate from digestibility values obtained at current field conditions were similar or somewhat high feeding levels are used. Digestibility values presented in earlier editions of CVB Feed Tables were based on animals that were fed at a level of approximately 705 kJ net energy (NE) per kg metabolic weight ($BW^{0.75}$). This corresponds to a feeding level of around 2.4 times maintenance. For further information, the reader is referred to the CVB Protocol for a faecal digestibility trial with growing, intact pigs (2005). For some feeds that are not regularly used in pig feeding no or only limited recent digestibility results have become available. In these cases the digestibility values were estimated using the old data or the combination of old and recent data. A general comparison between old and recent digestibility values suggested a systematic reduction in CP digestibility for the recent dataset of on avarage 4% compared to the old dataset. Therefore, for a number of feedstuffs for which no recent digestibility vales have become available the CP digestibility values were accordingly lowered in

CP digestibility. There was no systematic difference in crude fat digestibility between the old digestibility values and the recently obtained digestibility values, this also was the case for differences in NSP(h) digestibility between the old and the new dataset.

4.2.2.2 Origin of data on faecal digestibility of feedstuffs for growing pigs

In the current Feed Table, as much as possible digestibility results have been used from digestion trials carried out at Schothorst Feed Research (SFR) in Lelstad and the Animal Sciences Group (ASG) in Lelystad. For those feedstuffs were not enough recent data have become available the older results of trials performed in the past by the Food and Nutrition division of Wageningen UR Livestock Research in Lelystad, the Netherlands, (former IVVO-DLO and ILOB TNO) were used. Also, digestibility trials performed by Just (Denmark) and other literature results have been taken into consideration. For more information on how the the old database has been composed please read paragraph 4.2.2.2 in the Feed Table 2011).

4.2.2.3 Derivation of equations for calculating faecal digestible contents of CP, CFATh and NSPh

For all feedstuffs with net energy values for pigs given, equations have been developed for the calculation of the necessary contents of faecal digestible components (DCP, DCFATh and NSPh). These estimation equations are, for most feedstuffs, based on statistical analysis (regression analysis) of databases containing digestibility trials of individual feedstuffs or combined databases of related feedstuffs. For some feedstuffs, no or insufficient digestibility trials were available for statistical analysis. In those cases, the digestibility was estimated by comparing the chemical composition and other characteristics of the feedstuff with related feedstuffs with known digestibility figures obtained with growing pigs.
When deriving estimation equations, it is always investigated which components determine the digestibility of a certain component (e.g., the digestibility of CP is determined by the CP content, but often also by the CF or NDF content).
When deriving equations for digestible crude protein (DCP) and digestible crude fat (DCFATh), a basal endogenous faecal excretion of 12.5 g CP per kg DM and of 5.0 g CFATh per kg DM, respectively, was taken into account. For certain (purified) feedstuffs, basal endogenous faecal excretions were not expected to occur, and therefore were set to zero.

The digestible contents (e.g., DCP), calculated according to the above-mentioned product specific calculation rules, may be divided by the gross nutrient content, and subsequenltly multiplied by 100 (e.g., 100 * DCP/CP), resulting in the digestibility coefficient for that nutrient (in this case: DCCP). On the product sheets, the digestibility coefficient of CP, CFATh and NSPh – applying to the average chemical composition as stated on the product sheet - was calculated according to this procedure. For batches with a different chemical composition, this digestibility coefficient will not be correct. In those cases, the digestible nutrient content is better estimated by using the available specific calculation rules for that product.

For certain chemical components and feedstuffs, some specific remarks concerning the calculation of the energy value are made below.

4.2.2.4 Calculating the content of digestible crude fat

For feedstuffs with a low crude fat content (CFATh ≤ 15 g per kg DM), the digestibility of crude fat cannot be determined accurately in a digestibility trial. For such products, the content of digestible crude fat (DCFATh) is usually calculated with the following - pragmatic - equation:

[F.V01] DCFATh (g/kg DM) = a/100 x CFATh - 5.0

in which:

a	=	the true digestibility of the CFATh. For most feedstuffs it is assumed that a = 90%, except for leaf-rich feedstuffs (e.g., grass pellets or meal, alfalfa pellets or meal), where 'a' is set to 50%, because a substantial part of the CFATh in these feedstuffs consists of waxes and such (which are apparently digested, but are not utilized).
CFATh	=	the crude fat content in g per kg DM.
5.0	=	the above-mentioned endogenous basal faecal CFATh excretion (in g per kg DM).

4.2.2.5 Non-starch polysaccharides (NSPh)

For the energetic evaluation of feedstuffs for pigs, among other factors the calculated fraction 'non-starch polysaccharides' (NSPh) is used. The NSPh fraction consists of all carbohydrates (including pectin and lignin) with the exception of starch, sugars, glucose oligosaccharides (GOS), (volatile) organic acids, and ethanol. The following components are included in the NSPh fraction:

- The cell wall components cellulose, hemi-cellulose (including beta-glucans), pectin, and lignin.
- The non-starch polysaccharides including fructans (like inuline), galactans, and mannans.

4.2.2.5.1 Calculation of (D)NSPh in digestibility trials

The foundation for the NSPh digesibility values used in practise is, just as for CP and CFATh, digestibility studies. It is essential that a correct calculation takes place of NSPh and DNSPHh. Most dry feedstuffs do not contain (volatile) fermentation products. The NSPh fraction in dry feedstuffs therefore kan be calculated using the following equation:

[F.V02] NSPh = OM - CP - CFATh - STAam - GOS - CF_DI*SUG

(contents in g per kg DM)

The factor CF_DI in the equation F.V02 (and other equations) is a correction factor to convert the content of gross total sugars, expressed as glucose equivalents, into the sugar content as present in the product. Further explanation on the use of this correction factor is given in paragraph 4.2.3.5. For the calculation of DNSPh and NSPh always STAam should be used and not STAew (see paragraph 2.3.2).

Maize gluten feed contains substantial (but varying) amounts of lactic acid (LA). For a correct NSPh calculation the quantity of LA should be subtracted as well. Furthermore, DDGS contains besided LA also GLYCEROL and therefore in the calculation of NPSh for DDGS the amounts of LA and GLYCEROL should be subracted. Also dried industrial co-products coming from a wet procedure might contain products from an incomplete fermentation of starch (with a lenght of 2 – 10 glucose units). These are called glucose-oligosaccarides (GOS) and this fraction must be analysed seperately as these products are not detected in both the sugar analysis based on the Luff Schoorl method and the starch analysis based on an amyloglucosidase method or the Ewers method.
A number of high moisture industrial co-products contain substantial, but varying, amounts of fermentation products: lactic acid (LA), acetic acid (AC), propionic acid (PR), buteric acid (BU), ethanol (ETH), and in some cases also GLYCEROL. Also GOS may be present in substantial amounts in high moisture industrial co-products. Depending on the drying method used, part or all of the fermentation products LA, AC, PR, BU and ETH may evaporate during the drying process. In digestibility studies high moisture industrial co-products are freeze dried. The freeze drying method prevents the evaporation of LA although ETH evaporates completely. Furthermore, using the freeze drying proces only minimal amounts of the products AC, PR and BU evaporate and the degree of evaporation can be ranked as follows: BU > PR > AC. The ranking of the amount or presence of these fermentation products in high moisture industrial co-products is as follows: LA

> AC > PR. Considering the inaccuracy of the method used for analysing these fermentation products, these producs could be analysed in the freeze dried product. However, usually LA, AC, PR, BU and ETH are analysed in the non-dried product and then these analysed values are calculated to a DM basis. In order to do this it is important to realise that the accuracy of the DM method becomes more important at lower DM contents. The concentrations of GLYCEROL and GOS are, just as for ASH, CP, CFATh, SUG and STAam, analysed in the freeze dried product. The content of NSHPh in the freeze dried products of high moisture industrial co-products is calculated using the following equation:

[F.V03] NSPh = OM - CP - CFATh - STAam - GOS - CF_DI*SUG – LA – AC – PR – BU - GLYCEROL

- (contents in g per kg DM)
- (contents of LA, AC, PR and BU are normally analysed in the non-dried product and then calculated to concentrations on a dry matter basis.

The following nutrients are considered to be 100% digestible: STAam, GOS, SUG, LA, AC, PR, BU and GLYCEROL. For the calculation of the content of digestible NSPh (DNSPh) the starting point is the concentration of digestible organic matter (DOM) and from this DOM the digestible fractions of nutrients are subtracted.

For the dry feedstuffs without LA and GLYCEROL the following equation applies:

[F.V04] DNSPh = DOM - DCP - DCFATh - STAam - CF_DI*SUG

(contents in g per kg DM)

For moisture rich industrial co-products the equation is:

[F.V05] DNSPh = DOM - DCP - DCFATh - STAam - GOS - CF_DI*SUG - LA – AC – PR – BU - GLYCEROL

- (contents in g per kg DM)
- (contents of LA, AC, PR and BU are normally analysed in the non-dried product and then calculated to concentrations on a dry matter basis.

In digestibility trials, the digestibility coefficient of the NSPh fraction (DCNSPh) is always calculated according to the equation:

[F.V06] DCNSPh = 100 x (DNSPh / NSPh)

(contents in g per kg DM, DCNSPh in %)

4.2.2.5.2 Calculation of (D)NSPh in dry compound feedstuff samples in practice

In compound feedstuffs the presence of LA, GOS, GLYCEROL and volatile substances is not taken into account except for some exeptions. For the calculation of the NSPh content equation [F.V02] can be used: NSPh = OM - CP - CFATh - STAam - GOS - CF_DI*SUG. For the previously named feedstuffs maize gluten feed and DDGS also LA and LA + GLYCEROL should be subtracted, respectively.

4.2.2.5.3 Calculation of (D)NSPh in high moisture industrial co-product samples in practice

Analysis of high moisture industrial co-products in practise usually happens on samples that are not freeze dried but oven dried (see paragraph 2.4). the components ASH, CP, CFATh, STAam,

GOS and SUG are analysed in the dried product whereas the fermentation products are analysed in the non-dried product. The analysed fermentation components in the non-dried product are then converted to values expressed in the dry matter. The drying methods used in pracise results in the evaporation of part of the fermentation products. As a rule of thumb around 8% of LA and 50% of AC, PR and BU evaporate whereas GLYCEROL does not evaporate at all. For the calculation of the NSPh content than the following equation applies:

[F.V07] NSPh = OM - CP - CFATh - STAam - GOS - CF_DI*SUG – 0.92*LA – 0.5*(AC + PR + BU) - GLYCEROL

(contents in g per kg DM)

For the calculation of the DNSPh content the calculated NSPh using equation [F.V07] must be multiplied with the DCNSPh value (given on the product sheet) / 100.

4.2.3 Net energy values

This paragraph is divided in a number of subparagraphs, successively dealing with the calculation of net energy values for growing pigs (NE = net energy for growth), the NE value for sugar beet pulp products, rules for the calculation of DCP, DCFATh and DNSPh per feedstuff, and finally the energy value EW.

4.2.3.1 New equation for net energy for growth (NE_{2015})

This CVB Feed Table edtion starts with a new net energy equation to calculate net energy values (NE_{2015}) for feedstuffs. This equation has been derived from a dataset containg feed digestibility results of growing pigs from climate respiration chambers. This dataset has been given to CVB by J. Noblet from INRA (France). For more information on the development of this nieuw NE equation one can read CVB documentation reports 56 and 57 (2015). The new NE_{2015} equation is as follows:

[F.V08] NE_{2015} (kJ/kg DM) =
11.7*DCP + 35.74*DCFATh + 14.14*(STAam-e + GOS + 0.90*SUG-e) +
+ 9.74*FCH + 10.61*AC + 14.62*PR + 19.52*BU + 20.75*ETH +
12.02*LA + 13.83*GLYCEROL

The parameters used in equation [F.V08] are explained in Table 4.1.

Table 4.1 Explanation of parameters used in Equation [F.V08].

Parameter	Explanation	Calculation method per feedstuff
DCP	Digestible crude protein	Calculated based on analyzed CP content, using product specific equations or the digestibility coefficent presented on the product sheet / 100
DCFATh	Digestible crude fat (crude fat analyzed after acid hydrolysis)	In this new NE_{2015} the standard is CFATh. DCFATh is calculated based on the analyzed CFATh content, using product specific equations or the digestibility coefficent presented on the product sheet / 100
STAam-e	Enzymatically digestible starch	Only for potato products with (partly) native starch an enzymatical (ileal)

Parameter	Explanation	Calculation method per feedstuff
		digestibility of less than 100% is assumed (see also paragraph 3.2.3.4)
STAam-f	Fermentative degradable starch	STAam-f = STAam – STAam-e
SUG-e	Enzymatically digestible sugars	The content of enzymatically digestible SUG can be calculated by the equation: SUG-e = SUG*DCe-SUG/100. DCe-SUG is not mentioned in this Feed Table but can be calculated as follows: DCe-SUG = (SUG-e/SUG)*100 (see also paragraph 4.2.3.6)
SUG-f	Fermented sugars	SUG-f = SUG – SUG-e
CF_DI	Correction factor to convert the sugar content, expressed in glucose equivalents, into the sugar mass as present in the product	Value presented on the product sheet
FCH	Sum of fermented degradable carbohydrates	FCH = DNSPh + CF_DI*SUG-f + STAam-f
GOS	Glucose oligosaccharides	Value presented on the product sheet
AC	Acetic Acid	Only to be analyzed if a substantial content is expected, e.g., for certain high moisture industrial co-products
LA	Lactic Acid	
PR	Propionic Acid	
BU	Butyric Acid	
ETH	Ethanol	
GLYCEROL	Glycerol (Glycerine)	
DNSPh	Digestible non-starch polysaccharides	Calculated based on the calculated NSPh content, using product specific equations or the digestibility coefficent presented on the product sheet / 100

4.2.3.2 Explanation for the contribution of glucose oligosaccharides and fermentation products to NE_{2015}

Hereafter an explanation is given of the parameters GOS and the fermentation products AC, LA, PR, BU and ETH in equation [F.V08].

GOS consists of fragments of up to approximately 10 glucose units originating from an incomplete enzymatic degradation of starch. The net energy value of GOS equals that of starch. During the drying of a feedstuff no evaporation occurs.

For the stated organic acids, ethanol and GLYCEROL, the net energy value has been derived by comparing its ATP yielding potential with that of starch and by relating the proportion of the two to the NE_{2015} value of starch (see Table 4.2).

The contents of the organic acids and ethanol, as mentioned on the product sheets (also refer to paragraph 10.2), are determined in the non-dried ('fresh') product, and after that accounted for in the amount of dry matter that remains after drying of the sample. The above mentioned percentages of evaporation were estimated using literature data, and may in reality deviate from these values, due to the influence of factors like pH, method of drying and concentration. Currently there are not enough data available to estimate the extent of evaporation more accurately. These volatile components are only relevant for a number of high moisture industrial co-products feedstuffs and for maize gluten feed and DDGS.

Table 4.2 Net energy value and assumed evaporation during drying of some components mentioned in Equation [F.V08].

Component	Description	Real contribution NEv (MJ/kg)	Evaporation during drying of sample
GOS	Glucose oligosaccharides	14.14	0 %
AC	Acetic Acid	10.61	50 %
LA	Lactic Acid	12.02	8 %
PR	Propionic Acid	14.62	50 %
BU	Butyric Acid	19.52	50 %
ETH	Ethanol	20.75	100 %
GLYCEROL	Glycerol (Glycerine)	13.83	0 %

4.2.3.3 Compound feedstuffs generaly do not contain fermentation products

For the calculation of NE_{2015} according to [F.V08], the contents analysed in dry matter should be used. In dry compound feedstuffs fermentation products do not - or hardly – occur, and therefore the components AC, PR, BU, LA, ETH and GLYCEROL can be neglected. Also, GOS is not present in these materials in substantial quantities. The NE_{2015} equation [F.V08] can therefore be simplified:

[F.V09] NE_{2015} (kJ/kg product or g/kg DM) =
11.70*DCP + 35.74*DCFATh + 14.14*(STAam-e + 0.90*SUG-e) + 9.74*FCH

This equation results in NE_{2015} values expressed in kJ and can be used for the calculation of NE_{2015} on dry matter basis as well as on product basis (only if nutrient contents are expressed on a similar basis).

4.2.3.4 Native starch in potato products

The energetic coefficient for starch in the NE_{2015} equation (14.14 MJ/kg) is based on the assumption that all starch will be (enzymatically) degraded before reaching the terminal end of the small intestine (ileum).
One of the few starch types for which this definitely is not true is native or raw potato starch. Starch in potato products may be present as so-called "native" starch. Pigs are unable to digest native potato starch enzymatically, leaving it to be fermented (mainly in the large intestine). For products where this is the case, the starch content is corrected using a fixed factor (DCiSTA) to determine the NE_{2015}.
Depending on the treatment (especially heat treatments) that may be applied to potato products, starch will be more or less gelatinized and therefore better degradable in the small intestine. In this Table, potato products are divided into three categories:

1. Products in which the starch is completely gelatinized and 100% (enzymatically) degraded in the small intestine: DCiSTA = 100. This starch has an energetic coefficient of 14.14 MJ/kg.
2. Products in which half of the starch is (enzymatically) degraded in the small intestine and the other half is fermented in the large intestine: DCiSTA = 50. This implies that half of the starch is accounted for with the starch coefficient of 14.14 MJ/kg. The other half is integrated in the fermentative degradable remaining fraction; thus, this part is accounted for using a coefficient of 9.74 MJ/kg.
3. Products in which virtually all starch is in the native form, which is degraded exclusively by fermentation in the large intestine: DCiSTA = 0. The energetic coefficient equals 9.74 MJ/kg.

4.2.3.5 Correction factor for sugar (CF_DI)

In all CVB Tables (including this one), the sugar content is expressed in glucose equivalents. The content of crude total sugars (SUG) is determined according to Luff Schoorl. In this method the content of reducing sugars, soluble in 40% ethanol, is determined after hydrolysis with a diluted acid. With the hydrolysis of di- and oligosaccharides into monosaccharides, water molecules are bound, increasing the mass. In feedstuffs in which sugar is not solely present as monosaccharides, this will lead to an overestimation of the SUG content. The factor CF_DI was introduced to solve this problem: CF_DI is a correction factor for the conversion of the crude total sugar content, expressed in glucose equivalents, into the content in sugars as present in the feedstuff. For each feed ingedient CF_DI has a fixed value of at least 0.94 and at most 1.00. The value that is assigned to CF_DI for each feedstuff was derived from HPLC analyses of the crude total sugar content, yielding values for individual monosaccharides, disaccharides, trisaccharides and oligosaccharides. CF_DI is used for the correction of SUG in the equations for the calculation of NSPh [F.V02], [F.V03] and [F.V07] and DNSPh [F.V04] and [F.V05], and for the correction of SUG-f in the corresponding NE_{2015} equations [F.V08] and [F.V09].

4.2.3.6 Digestibility of sugars

SUG-e consists of the sum of glucose and other sugars that are digestible by digestive enzymes of the pig (sucrose, lactose, maltose). In comparative analyses, it has been observed for a number of feedstuffs that the content of reducing sugars, determined by Luff Schoorl, differs from the sum of glucose content and sucrose content (and maltose content). If this is the case, the reducing sugar content determined according to Luff Schoorl is corrected, using the factor SUG-e/SUG from the table. When both contents do not differ, SUG-e/SUG is set to 1.0.
In lactose containing products a SUG-e/SUG value of 1.0 will also be used. Growing and finishing pigs (25 kg and over) do not produce any lactase if the ration does not contain any lactose. If lactose is introduced to these pigs, lactase synthesis is induced again. The adaptation period to rations that contain lactose is approximately 7 days. Consequently, the factor of 1.0 will only apply if lactose containing diets are regularly provided.

4.2.3.7 The NE_{2015} equation is based on respiratory trials with growing pigs

The until recently used NEv equation was, just as the earlier NEv equation of Schiemann et al., (1971) (where the carbohydrate fraction was partitioned in digestible CF and digestible NFE), based on results from respiratory metabolism trials with heavy pigs that mainly deposited fat (Schieman et al., 1971). These NEv equations resulted in overprediction of the true deposited energy when being used for a more modern pig (Van der Honing et al., 1984). This NE2015 equation is based on respiratory metabolism trials carried out by J. Noblet from INRA (France) with growing pigs (CVB documentation report 56, 2015).

4.2.4 The NEv value of sugar beet pulp products

Research on growing pigs receiving rations containing 0 - 15 % pressed sugar beet pulp (ensiled), on a feeding level of 2.5 times maintenance level, showed that an increasing beet pulp

fraction in the ration resulted in a decrease of the physical activity of the animals, and therefore also the maintenance requirements. Similar research showed that feeding dried sugar beet pulp also reduced physical activity. Therefore, the energy value of sugar beet pulp products in practice is higher than calculated with equation [F.V08] or [F.V09]. For rations containing up to 15 % dried sugar beet pulp or pressed sugar beet pulp (fresh and ensiled), the energy value should be calculated as follows:

[F.V10] Energetic utility value = NE_{2015} (calculated according to [F.V08] or [F.V09] + 3.9 x DNSPh

with Energetic utility value and NE_{2015} in kJ/kg, DNSPh in g/kg (dried sugar beet pulp), or Energetic utility value and NE_{2015} in kJ/kg DM and DNSPh in g/kg DM (pressed sugar beet pulp)

The NE_{2015} and EW_{2015} values, as mentioned on the product sheets of sugar beet pulp products, have been calculated using this equation.

4.2.5 The EW value

The energy value of feedstuffs for pigs can be expressed as NE_{2015}, but also as a proportional number EW_{2015} (EW = Dutch abreviation of energy value), where the NE_{2015} of the feedstuff is divided by the mean net energy value of one kg of a compound pig feed as commonly produced around 1970 (NEv = 8.8 MJ/kg):

[F.V11] $EW_{2015} = NE_{2015}$ (in MJ) / 8.8 MJ

Although the calculated NE_{2015} value of a diet is higher than the NEv value of the same diet it has still been decided to maintain the in the old NEv system used conversion factor of 8.8.

4.2.6 The energy value of fermentation products and amino acids

4.2.6.1 Estimation of the energy value of fermentation products based on their ATP yielding capacity

The energy values of fermentation products cannot be determined in animal trials, since this kind of study requires high contents in the ration and because high amounts of these products are mostly not accepted by the animals. One method to estimate the energy value of these products is to estimate their theoretical ATP yielding capacity and compare this value with the ATP yielding capacity of starch.
The maintenance metabolism of an animal is mainly a matter of ATP expenditure and also in production metabolism the ATP yielding potential plays a role.
For the estimation of energy values based on the ATP potential, a certain compound is used as a reference, to which all products are compared. The reference compound used in this calculation is starch; the ATP yield (moles) per gram of starch is known and set to 100%. The ATP yield (moles) per gram of the other compounds is expressed as a percentage of the ATP yield of starch. Based on this percentage, the energy value is calculated.
For example: Starch has an ATP yielding capacity of 0.2222 moles of ATP per gram matter. The ATP yielding capacity of propionic acid is 0.2297 moles per gram, so 3.38% more. The energy value of 1 kg of pure starch for pigs is 14.14 MJ NE_{2015}. The energy value of 1 kg of pure propionic acid is, therefore, 1.0338 x 14.14 = 14.62 MJ NE_{2015}.
For glucose, sucrose and starch, the ATP potential per glucose unit is equal. During polymerisation of glucose molecules through glucosidic bindings, however, one water molecule is removed from each glucose molecule. Therefore, the ATP potential of a free glucose molecule is 0.90 x that of a glucose molecule within a starch molecule; likewise, for sucrose a factor 0.95 applies.

The energy values that are derived in this way for fermentation products, glucose and sucrose for different animal categories are given in paragraph 10.5 ‘Miscellaneous’.

4.2.6.2 Estimation of the energy value of synthetic amino acids

For synthetic amino acids, also the estimated ATP yielding capacity is used as a starting point. By comparing the ATP yield of these amino acids with the ATP yield of starch, the energy value can be calculated. For the calculation of the NE_{2015} vaules of amino acids the publication of van Milgen (2012) is used. See further paragraph 10.5 ‘Miscellaneous’.

4.3 Protein value

When equationting a diet, it is of importance, as far as protein is concerned, to take into consideration a number of aspects:

- First, for the conversion of feed protein into body protein, it’s not the content of protein as such that is relevant, but the amino acid profile of the protein in a feed.
- Second, it is not the amino acid profile as such that is important, but the digestibility of the various amino acids. In feedstuffs with a low crude protein digestibility, the digestibility of the separate amino acids may vary substantially.
- Third, only the amino acids that have been digested and absorbed before the end of the small intestine (=ileum) can be utilised by the pig. Amino acids that pass the small intestines into the large intestine with the digesta, can be degraded, or converted into other amino acids by means of microbial fermentation in the large intestines, but do not contribute to the provision of amino acids to the animal.
- Fourth, it should be emphasized that a digestibility trial using a test diet always yields apparent digestibility. This means that the digesta collected at the terminal ileum not only contains undigested feed protein, but also undigested protein of endogenous origin.

Especially the third aspect has resulted in the introduction in 1990 by CVB of the ‘intestinal digestible amino acids’ system for the determination of protein values in feedstuffs for pigs. This system was based on the apparent small intestinal (or ileal) digestibility of amino acids in feedstuffs:

[F.V12] Apparent ileal digestibility AA (%) =
{(AA intake) - (AA that leave the ileum undigested)} x 100 / (AA intake)

4.3.1 Determination of apparent ileal digestible amino acids in cannulated pigs

In research performed in the Netherlands, the determination of the contents of apparent ileal digestible amino acids was, and still is, done in pigs that have been fitted with a cannula at the end of the ileum. With this technique, it is possible to collect digesta at the end of the ileum. The apparent ileal digestibility of an amino acid is the fraction of the amino acid in the ingested feed that is not retrieved from the digesta collected at the end of the ileum, plus the amount of undigested endogenous protein present in the digesta.
The digesta is not collected quantitatively. In order to be able to relate this non-quantitatively collected amount to a certain amount of ingested feed, an inert marker is added to the feed. Using the contents of this marker in feed and digesta, the ‘apparent ileal digestibility’ can be calculated.

4.3.2 Endogenous losses

4.3.2.1 Origin of endogenous losses

The digesta not only contains amino acids from undigested feed protein, but also from undigested proteins of endogenous origin.
The non-digested endogenous protein fraction is composed of proteins from:

- undigested enzymes from digestive juices,
- desquamated epithelium cells,
- the mucus,
- bacterial protein, arising from fermentation.

4.3.2.2 Basal endogenous protein vs specific endogenous protein

The endogenous protein excreted into the gastrointestinal tract can be separated into:

a. basal endogenous protein
b. endogenous protein, induced by feed-specific factors, also known as 'specific endogenous protein'

Therefore, the undigested endogenous protein that leaves the small intestine, can be subdivided as follows:

[F.V13] $uCP_{i\text{-}endogenous}$ (g/kg feed) = $uCP_{i\text{-}basal}$ + $uCP_{i\text{-}specific}$

where:

$uCP_{i\text{-}endogenous}$ = total amount of undigested endogenous protein that passes the ileum.
$uCP_{i\text{-}basal}$ = amount of undigested basal endogenous protein (expressed as g/kg ingested feed) at the end of ileum.
$uCP_{i\text{-}specific}$ = amount of undigested endogenous protein (g/kg feed), induced by feed specific factors, at the end of the ileum.

The 'basal endogenous protein' is the endogenous protein that is secreted into the gastrointestinal tract due to the passage of "feed". More information on how to take the excretion of undigested basal endogenous protein into consideration when evaluating ileal protein and amino acids is given in paragraph 4.3.4.

In the feed, factors may be present that induce an additional secretion of (specific) digestive enzymes, the production of more mucus proteins that cover the epithelium of the intestinal lumen, and/or an extra sloughing off of the epithelium of the small intestine. The most important feed specific factors that cause the secretion of specific endogenous proteins, belong to the so-called "Anti Nutritional Factors" (ANF's), that can be found in, for instance, legume seeds. Also, fibre-rich feedstuffs cause damage to the mucus layer and hence will lead to an increase in undigested mucus proteins.
Currently it is not possible, in practice, to correct for the amount and the amino acid profile of the undigested specific endogenous protein, when evaluating ileal protein and amino acids, with the use of specific calculation rules.

4.3.3 True ileal digestibility of amino acids

After adjusting the amount of undigested amino acids at the end of the ileum for the amount of undigested amino acids of endogenous origin, only the amount of undigested amino acids from the feed remains. The difference between the amount of ingested amino acids and the amount of amino acids from the feed that is excreted in the digesta is considered to be truly digested (see [F.V14]). As there is no practical method yet to calculate the excretion of undigested specific endogenous protein adequately, the true ileal digestibility has not yet been implemented in practice.

[F.V14] True ileal digestibility (AA) (%) =

{(AA intake) - (AA that leave the ileum undigested - AA endogenous)} x 100
(AA intake)

4.3.4 Standardized ileal digestibility amino acids

It is possible to adjust the apparent digestibility for the excretion of undigested basal endogenous protein. This fraction is generally related to the amount of dry matter intake. For a number of years, the composition of basal endogenous protein has been used based on on a literature study (Jansman et al., 1997; Jansman et al., 2002). The German "Gesellschaft für Tierernährungsphysiologie" (2005), however, stated that two of the research techniques included by Jansman et al. should be omitted. In 2006, the former CVB Working Group Feed Table agreed with the German argumentation, and decided to make use of the composition of endogenous protein as given in Table 4.3.

Table 4.3 Composition of basal endogenous protein that leaves the terminal ileum undigested (contents in g/kg dry matter intake).

Crude protein	11.43	Leucine	0.47
Lysine	0.39	Tyrosine	0.29
Methionine	0.11	Valine	0.53
Cystine	0.21	Alanine	0.49
Threonine	0.59	Aspartic Acid	0.78
Tryptophan	0.14	Glutamic Acid	1.17
Isoleucine	0.37	Glycine	0.90
Arginine	0.39	Proline	1.10
Phenylalanine	0.32	Serine	0.65
Histidine	0.18		

The apparent protein or amino acid digestibility that has been corrected for the excretion of undigested basal endogenous protein is usually called 'standardized digestibility' (see [F.V15]):

[F.V15] Standardized ileal digestibility amino acids (AA) (DSta-i-AA, in %) =

{(AA intake) - (AA undigested at end ileum - AA undigested basal endogenous protein)} x 100
(AA intake)

With the amino acid content and apparent digestibility determined in digestibility trials, and the above-mentioned amino acid losses through basal endogenous protein, the values for the standardized ileal digestibility (StaVCi) of the crude protein and the amino acids have been calculated for the various feedstuffs for pigs. In this table, for each individual feedstuff, the content of 'standardized ileal digestible protein/AA' and the content of 'apparent ileal digestible protein/AA' both are given.

4.3.5 Origin of the data on ileal digestible amino acids in feedstuffs

The data in this table are based on a thorough screening of literature by ILOB-TNO, by order of Degussa AG (Germany), in 1997/1998. The collected data, and the calculations performed on them, have been made available unconditionally to CVB. The former CVB Working Group Feedstuff Table has tested objectively if the data were useful for the revision of amino acids evaluation for pigs. The accumulated trials were checked for a number of criteria on their reliability before being included in the database.
After it became clear that the data obtained with the so-called Ileal Rectal Anastomosis (IRA) technique (whereby the end of the ileum is surgically connected to the rectum; often used in France) did not substantially differ from data obtained with the cannulation technique, these trials were also entered in the database.

In literature a large number of digestibility trials has been described where the raw material to be studied was the only source of protein in the diet. By adjusting the apparent ileal digestibility of the *diet* in these cases for the basal endogenous production that is caused by the fraction of protein free feedstuffs, the apparent ileal digestibility of the *examined protein source* is obtained. After this correction, these data were also included in the database.
Different digestibility trials in the database, conducted with different batches of the same feedstuff, show some variation with respect to the apparent digestibility of amino acids. This is partly due to differences in digestibility between batches. For another part the variation is due to differences in protein content and the analyzed amino acid profile in different batches. Assuming an equal digestibility for the feed protein, these last differences lead to variations in the contribution of the undigested endogenous protein in the total pool of undigested protein in the digesta. By converting the reported apparent digestibility to standardized digestibility, values are obtained for the digestibility of protein/amino acids that do not depend on the fluctuations of protein or amino acids contents in the feedstuff, at an equal digestibility of the feed protein.
For each raw material, the standardized digestibility of protein and amino acids has been calculated according to this method.
Because of the fact that the passage of dry matter leads to (at least) the excretion of undigested basal endogenous protein, for protein free materials (such as fat, starch, sugar), a negative value - instead of zero digestibility - is obtained for the digestibility. This negative digestibility value equals the basal ileal endogenous excretion.
Apart from the above-mentioned literature screening by ILOB-TNO, for some feedstuffs additional information has become available and incorporated in the database.
For a number of feedstuffs, (practically) no data were available. In those cases where also equations are given for the calculation of NEv, the ileal crude protein and amino acids digestibility of these feedstuffs has been estimated. In all cases, this applies to feedstuffs that are quantitatively less important in pig feeds.

Based on the data that are available at present, it may be assumed that separately added free amino acids have a true ileal digestibility of 100%. A correction per kg for the excretion of basal endogenous protein is needed to make comparisons based on apparent ileal digestibility. Also, the fact that synthetic amino acids are sometimes put on the market in the form of salts should be taken into account: In these cases, only part of the product consists of the amino acid, and one should proceed from the amino acid content in the product, as guaranteed by the manufacturer.

4.3.6 Contents of standardized and apparent ileal digestible amino acids

In order to reach an accurate estimation of the ileal digestibility of amino acids for pigs, based on the available digestibility trials, the standardized digestibility of the various trials was calculated and averaged for each feedstuff and each amino acid.
Thus, for each amino acid, the content of standardized ileal digestible amino acid can be calculated, provided that the amino acids contents in the feedstuff are known. The contents of standardized ileal digestible amino acids are given on the product sheets of the separate feedstuffs.
In the Netherlands - as opposed to other countries - until now, apparent ileal digestible amino acid contents have always been used in practice to evaluate feedstuffs and to calculate amino acid requirements. That is why these contents are also included in the product sheets.
The content of apparent ileal digestible amino acid (in dry matter) can simply be calculated by subtracting the content of basal endogenous amino acid (see Table 4.3) from the content of standardized ileal digestible amino acid (also expressed on dry matter basis), as follows:

[F.V16] Content of apparent ileal digestible AAx =
Content of standardized ileal digestible AAx - Content of basal endogenous AAx
(contents in g per kg DM)

4.3.7 Requirements of standardized and apparent ileal digestible amino acids

For the requirements of standardized and apparent ileal digestible amino acids for pigs in various stages of growth and production, please refer to the most recent version of the CVB Tables Animal Nutrition.
It is up to the user of this Table to decide whether he will use standardized or apparent ileal digestible amino acids in diet equationtion. **However, it is emphasized that one has to make one and the same choice for both the supply of ileal digestible amino acids by the feed, and the requirements of the animals.**

4.4 Digestibility of phosphorus

In the Netherlands (and other countries) it is quite common to take into account the (faecal) digestibility of P in determining the phosphorus (= P) requirements in pigs. The P digestibility may vary greatly between feedstuffs.
Untill the CVB Feed Table edition of 2011 'apparent fecal digestible P' was used. Internationally, in most cases for digestible P 'standardized fecal digestible P' is used in which the apparent fecal digestible P is corrected for endogenous P losses. In order to join the international conventional method of using standardized fecal digestible P it was decided to use in the CVB Feed Table 2016 edition standardized fecal digestible P values as well. An extra reason for changing to standardized P values was the fact that in the previously by CVB used apparent P digestible system part of the endogenous P losses was accounted for in the P requirement recommendations resulting in a double counting of endogenous P. Simultaneously, with the change to standardized digestible P (StaDCP) also the requirement recommendations for StaDCP and Ca will become updated and described in an upcoming WUR-LR report.
In the P digestibility research feedstuffs of vegetable and animal origin were considered, as well as inorganic hosphates. Recent digestibility studies have resulted in extra data on P digestibility of mainly plant based feedstuffs. This means that the database with in vivo data on P-digestibility has been extended considerably. The StaDCP for all digestibility studies was calculated from the measured apparent digestible P and the dietary P content of the feedstuff of interest:

[F.V17] StaDCP = ((AppDCP / 100 * P + 0,20) / P) * 100.

StaDCP in %, AppDCP (apparent digestibility coefficient of P) in %, P in g/kg DM

Then the experimental StaDCP values per feedstuff were averaged and the average values are presented on the product sheets. In case, for a feedstuff, there were less than 5 records the average value was rounded to the closest fivesome.
To make a comparison possible between digestible P values used in previous editions and the present StaDCP values as well the apparent digestible coefficents (AppDCP) are presented. These AppDCP were calculated as follows: a) the P concentration on the product sheet in g/kg is calculated based on the DM content presented on the product sheet to concentration of P in g/kg DM; b) using the presented StaDCP and the P content expressed in g/kg DM the concentration of standardized digestible P (StaDP is calculated; c) from the StaDP the quantity of endogenous P (0.20 g/kg DM) is subtracted in order to calculate the concentration of apparent digestible P (AppDP) is calculated; d) using the P concentration in g/kg DM and the value for AppDP the percentage of apparent digestible P (AppDCP) can be calculated.
For a number of feedstuffs, that are less relevant for pigs, little or no observational data concerning digestibility of P are known; sometimes the digestibility of P was estimated and derived from that of related feedstuffs.
Information on dietary phosphates is included in paragraph 10.4 (Mineral feedstuffs). A distinction has been made between mono- and dicalcium phosphates (hydrous and anhydrous), and other dietary phosphates.
Some vegetable feedstuffs contain considerable amounts of the enzyme phytase, which is capable of (partially) releasing inositol bound phosphorus and thus making it absorbable. Also, products have been available, for several years now, containing phytase of microbial origin.

Phytase has a strong positive effect on the P digestibility of feedstuffs of vegetable origin. However, the temperature sensitivity and pH dependence of these enzymes has to be taken into consideration. When during steam pelleting the temperature of the pellet exceeds 80°C, the phytase activity may decrease strongly, depending on the type of phytase preparation (e.g., whether the enzyme is coated or not). The pH dependence can be of importance when organic acids are added to the compound feed or ration, or when wet feedstuffs are provided that contain wet fermented feedstuffs. The exact relationship between the pH in the ration and the effectiveness of vegetable phytase in the relevant pH range, however, is not yet known. With respect to the relationship between pH of the ration and microbial phytase, one should consult the supplier of the phytase product concerned.
In the values, as listed in the Table, it is assumed that there is no endogenous phytase activity present in the feedstuff. This approach is of importance for barley, rye, wheat, triticale and their co-products. Whenever values for the digestibility of P without pelleting were available (and therefore in the presence of natural phytase activity), these are noted as a comment on the product sheet.

4.5 Calculation examples

For calculation examples, with step-wise explanation of the calculation of the feeding values within the various systems for pigs, see document RD007 on the CVB website: www.cvbdiervoeding.nl.

5. FEED EVALUATION SYSTEMS FOR POULTRY

5.1 Feed evaluation systems

In this Chapter the feed evaluation systems of CVB for poultry are described. For poultry, three types of feed evaluation systems have been established by CVB:

- Energy systems (paragraph 5.2)
- A protein / amino acids system (paragraph 5.3)
- A digestible phosphorus system (paragraph 5.4)

5.2 Energy systems

5.2.1 Metabolizable energy system for adult animals

5.2.1.1 Digestibility figures

The digestibility coefficients given in the tables for crude protein, crude fat, and nitrogen free extract have been derived from experiments with adult cocks, in which it was determined which part of the ingested feedstuff does not appear in the faeces, and is therefore apparently digested. The energy contribution of crude fibre is assumed to be negligible, since crude fibre is indigestible by poultry.
The energy value (ME = Metabolizable Energy) determined in adult cocks is expressed by the abbreviation MEpo (= ME poultry). This value may also be used for other types of poultry, like turkeys and ducks. MEpo is also often applied as a declaration of the energy value when exporting poultry feeds.
Digestibility figures are mostly derived from research at the former Centre for Research and Information for the Poultry Industry (COVP-DLO). Literature data have also been used.

The experiments performed to establish the MEpo-value of feedstuffs were also used to verify the digestibility coefficients derived from the available data. When the equation:

[F.P01] MEpo (MJ/kg) = (18.03 x DCP + 38.83 x DCFAT + 17.32 x DNFE) / 1000

or

[F.P02] MEpo (kcal/kg) = 4.31 x DCP + 9.28 x DCFAT + 4.14 x DNFE

(with the contents of DCP, DCFAT and DNFE in grams per kg)

led to an MEpo differing from the value derived from animal experiments, the digestibility figures were adjusted in the CVB Feed Table according to the deviation.

For most feedstuffs it is common practice to predict the MEpo value directly from their chemical composition, using a product specific regression equation. Nevertheless, also for these feedstuffs, the product sheet states the digestibility coefficients in the column ‘Cocks’. When these digestibility coefficients are adequately attuned to the product composition, equation F.P01 or F.P02 should result in approximately the same MEpo value as the product specific regression equation. However, from 1991 onwards, the composition of many feedstuffs has more or less changed. Because in many cases information on nutrient digestibility was no longer available, digestible nutrient contents could no longer be updated according to these data. Instead, an adjustment of the digestible nutrient contents based on a rational approach was pursued, to

obtain similarity between the MEpo value calculated using equation F.P01 or F.P02, and the MEpo value calculated via the product specific equation.
Calculation of the ME value with the product specific equations remains the preferred method.
In some cases, also the digestible nutrient contents have been adjusted of products for which no product specific equation exists, because the formerly in CVB tables stated values (mostly based on limited research) could not always be rationally explained.
Adjustment of the digestible crude protein content according to the method described above, and deriving (faecal) amino acids digestibility from crude protein digestibility, also leads to an adjustment of the stated content of (fecal) digestible amino acids.

5.2.1.2 Energy value for adult roosters

Digestibility trials with adult roosters have been the basis for deriving ME values of feedstuffs for adult roosters and laying hens already for many years. In these trials, the combustion value (Gross Energy content) of the ingested feedstuff and the combustion value of faeces and urine, corrected for N balance, have been determined.
Depending on the available information, different procedures were subsequently followed to develop equations for calculating ME for adult roosters.

A. Regression analysis based on animal experiments with (mainly) Weende analysis parameters as explanatory variables.

Results of animal trials performed by COVP-DLO, INRA (Tours, France) and PRC (Rosslin, Scotland) could be used for this analysis.
When the MEpo value for a feedstuff was calculated using a product specific regression equation, derived in this way, equations F.P01 or F.P02 were subsequently used to adjust the digestibility coefficients to this MEpo value.
The regression equations below apply to MEpo values and contents (g per kg DM).

- Barley

[F.P03] MEpo (MJ) = (9258 – 9.258*ASH + 7.709*STAam) / 1000

- Oats

[F.P04] MEpo (MJ) = (12980 – 12.98*ASH + 48.82*CFAT – 25.50*CF) / 1000

- Barley products (excluding barley)

[F.P05] MEpo (MJ) = (13740 – 13.74*ASH – 35.58*CF + 2.988*STAam) / 1000

- Products from maize milling industry and maize starch production

[F.P06] MEpo (MJ) = (17538 – 17.54*ASH – 7.569*CP + 17.27*CFAT – 75.42*CF) / 1000

- Rice products (including rice)

[F.P07] MEpo (MJ) = (19540 – 19.54*ASH – 29.1*CP + 17.97*CFAT – 34.29*CF) / 1000

- Wheat products (excluding wheat)

[F.P08] MEpo (MJ) = (16780 – 16.78*ASH – 69.20*CF) / 1000

- Tapioca

[F.P09] MEpo (MJ) = (16380 – 16.38*ASH – 34.64*CF) / 1000

- Sunflowerseed products (CF < 280 g/kg DM)

[F.P10] MEpo (MJ) = (2626 – 2.62*ASH +10.62*CP + 26.20*CFAT) / 1000

- Meat meal and meat and bone meal

[F.P11] MEpo (MJ) = (14200 – 19.15*ASH + 25.1*CFAT) / 1000

- Soybean meal and soybean expeller (for 154 ≤ CP ≤ 706; 29 ≤ CF ≤ 369; 4 ≤ CFAT ≤ 85 (in g/kg DM)

[F.P12] MEpo (MJ) = (7690 – 7.69*ASH + 6.464*CP + 29.43*CFAT – 16.09*CF) / 1000

B. In a number of cases, the digestibility data were not suitable for regression calculation. The chemical composition could be divided into, e.g., three groups that were sufficiently representative for some qualities. By solving equations, a linear curve was calculated using the means of those three groups. This curve was then used to estimate the MEpo value

- Fullfat peanuts and peanut products

[F.P13] MEpo (MJ) = (12420 + 25.50*CFAT – 25.47*CF) / 1000

- Cottonseed products

[F.P14] MEpo (MJ) = (8898 + 19.72*CFAT – 12.91*CF) / 1000

C. Processing of results of French research, determining the MEpo value of different batches of sorghum with varying contents of tannins, resulting in the following regression equation:

- Sorghum

[F.P15] MEpo (MJ) = 16.13 – 1.65*%tannins
(tannins content determined according to Kuhla and Ebmeyer, 1981)

This regression line could not be included in the Table. It was, however, used to calculate the MEpo value of the low tannin sorghum type that have been included in this Table.

D. Other equations:

- Molasses (sugarcane and sugarbeet)
  For these products the energy value is calculated based on the sugar content (expressed as glucose units) according to the following equation:

[F.P16] MEpo (MJ) = (16.45*SUG) / 1000 (SUG in g/kg)

- Calculation equation for fat from Dutch destruction plants

[F.P17] MEpo (MJ) = 83.9 – 0.0962*IV – 0.1335*(C16:0) – 0.06418*(C18:0)

In which: IV = Iodine value

C16:0 = g palmitic acid per 1000 g total fatty acids
C18:0 = g stearic acid per 1000 g total fatty acids

This equation applies to the MEpo calculation of fats and oils, and not for mixtures of fatty acids.

5.2.1.3 Energy value for laying hens

From comparative research on adult roosters and laying hens by Scheele et al. (1985) it appears that the utilization of the ME from fat for maintenance and production is approximately 15% higher for laying hens compared to roosters.
In 1986, it was decided to express this difference in feeding value calculation and to refer to the energy value standard for laying hens as “MEla”.
For raw materials of which the MEla is calculated from digestibility coefficients, equations F.P01 and F.P02 were adjusted as follows:

[F.P18] MEla (MJ/kg) = (18.03 x DCP + 44.65 x DCFAT + 17.32 x DNFE) / 1000

or

[F.P19] MEla (kcal/kg) = 4.31 x DCP + 10.67 x DCFAT + 4.14 x DNFE

(with contents of DCP, DCFAT and DNFE in grams per kg)

in which the coefficient for the factor DCFAT equals:

in MJ: 38.83 x 1.15 = 44.65.
in kcal: 9.28 x 1.15 = 10.67

To convert the calculated MEpo to MEla, the MEpo should be increased
- In MJ by: (0.15 x 38.83 x DCFAT) / 1000 = 5.8 x DCFAT / 1000
- In kcal by: (0.15 x 9.28 x DCFAT) / 1000 = 1.39 x DFAT / 1000

5.2.2 Broilers

5.2.2.1 General

From comparative research at the former COVP-DLO (Beekbergen, The Netherlands) it appeared that the feeding value of fat for broilers is lower than for adult roosters. Also for other materials differences in ME values were found between broilers and adult roosters, although these differences were generally smaller than for fat. In 1990, this has led to the implementation of a separate ME evaluation (MEbr) for broilers (CVB series no 1, 1990). The table published at that time included the results of the digestibility research from COVP-DLO on raw materials that were the main constituents of practical broiler diets. In practice, however, doubts existed concerning the valuation for various feedstuffs. In the nineties, this led to extensive basic research, aimed at the equationtion of a standard protocol for digestibility trials with broilers. After completion of this protocol, the faecal nutrient digestibility of a large number of feedstuffs has been determined. In this edition of the Feed Table, the results of four projects studying the digestibility of feedstuffs for broilers have been implemented, to obtain a better estimation of MEbr for the feedstuffs concerned. In this Table, the MEbr equation that was introduced in 1991 is abandoned, and a new equation is introduced with the same energetic coefficients as used in the MEpo equation (see paragraph 5.2.2.3.1). A third adjustment that is introduced from this edition onwards concerns the calculation of the digestible carbohydrates fraction (see paragraph 5.5.5.3.2).

5.2.2.2 Digestibilities

The digestibility coefficients are derived from trials with young broilers, executed by order of CVB, according to the CVB protocol for faecal digestibility trials with broilers. In this study, the digestibility of organic matter (OM), crude protein (CP), crude fat (CFATh) and - in many cases - also starch (STA) was determined. The feedstuffs investigated in this study have been analysed for DM, ASH, CP, CFATh, CF, SUG, and STAam.

5.2.2.3 Energy value

5.2.2.3.1 Metabolizable energy value of digestible crude protein

Up to the previous edition of the Feed Table (2007), the MEbr of feedstuffs was calculated according to the following equation:

[F.P20] MEbr (MJ/kg) = (15.56 * DCP + 38.83 * DCFATh + 17.32 * DNFEh) / 1000

Or:

[F.P21] MEbr (kcal/kg) = 3.72 * DCP + 9.28* DCFATh + 4.14 * DNFEh

(with contents of DCP, DCFATh and DNFEh in g per kg)

This equation is derived from multiple regression analysis on the results of a COVP-DLO study, executed in the nineteen eighties, investigating the nutritional value of 15 important feedstuffs. In this study, the digestibility of CP, CFATh and NFE was determined, and the ME value (corrected to N balance) was also assessed. The regression model contained the amounts of digestible crude protein, crude fat and N-free extract as explanatory variables. From this study it was found, that the coefficients for digestible fat and digestible N-free extract did not differ markedly from the coefficients that had been derived from a comparable study with adult roosters.

Ever since the introduction of the above-mentioned MEbr equation, discussion has arisen concerning the correctness of the energetic coefficient for DCP in this equation – this coefficient cannot be explained physiologically. Assuming a gross energy content for protein of 23.6 MJ/kg, a complete metabolisation of protein to water, carbon dioxide, uric acid (and urea), a complete excretion of uric acid (and urea) with excreta, and a 'gross energy value of uric acid, calculated to CP' of 5.6 MJ/kg, the ME coefficient for protein should amount to approximately 18 MJ/kg. It is also unlikely that the ME value for digestible crude protein with broilers – assuming complete metabolisation – should differ from that with adult roosters and laying hens.
Multiple regression on the results of the various trials that were performed by order of CVB to establish the digestibility and ME value of feedstuffs for broilers, and regression analysis on the total database, revealed that the derived energetic coefficient was always higher than the previously used coefficient of 15.56 (equation [F.P20]). It should also be stressed that this coefficient was always lower than 18.03, the energetic coefficient for DCP in the MEpo equation. Although no satisfactory explanation was found for the latter, it was decided to calculate MEbr using an energetic coefficient for DCP of 18.03 MJ/kg.

When determining the fat digestibility, crude fat was analysed in feed and in excreta after acid hydrolysis. To calculate MEbr, one should always use CFATh.

5.2.2.3.2 New classification of carbohydrates fraction for calculating MEbr

Concerning the carbohydrates fraction, in the past it was always assumed that the digestibility of crude fibre was negligible (DCCF = 0), and only the digestibility of the N-free extract was taken into account. However, within different batches of one and the same feedstuff, the proportion of starch, sugars and fibrous components varies. Of these carbohydrates, starch and sugars are (very) highly digestible, whereas the digestibility of the fibrous fraction will be low. Using one fixed

digestibility coefficient for the NFE fraction does not account for the variation in composition of the NFE fraction.
At first, CVB aimed to divide the NFE fraction in a starch fraction (STA), a sugars fraction (SUG), and a non starch polysaccharides fraction (NSP), according to the procedure used for pigs. In poultry, however, the digestibility of the NSP fraction is low. Also, the (D)NSP fraction is a calculated fraction, implying that all (mainly analytical) errors accumulate in the (D)NSP fraction. Thirdly, the factor 6.25, used to calculate crude protein content from analysed N content, is too high for a number of feedstuffs. This implies that part of the NSP fraction is contained in the CP fraction. Especially in protein-rich feedstuffs, this may be a considerable amount. For these reasons, this option was abandoned.

The SUG fraction in feedstuffs consists of enzymatically digestible and fermentative degradable sugars. Excreta of animals fed with a relatively SUG-rich feed contain hardly any sugars, indicating that the SUG fraction is highly digestible. Of dietary starch, also only a few percents were recovered from the excreta. It was assumed that all glucose equivalents retrieved from the excreta were derived fron undigested starch. It is, however, not clear whether the fermentation products - that are formed in the caeca as a result of microbial degradation of fermentable sugars and of ileal undigestible starch – are completely absorbed, or partly excreted with the excreta. Also, in the caeca, some fermentation will occur of (mainly water soluble components in) the NSP fraction. Based on these considerations, it was decided to define the digestibility of the carbohydrates fraction as follows:

[F.P22] DC(STAam+SUG) = (DOM–DCP–DCFATh) / (STAam+CF_Di*SUG) * 100%

5.2.2.3.3 Presence of fermentation products in feedstuffs for poultry

From analysis it appeared that considerable amounts of lactic acid (LA) are present in wheat glutenfeed, and especially in maize glutenfeed. Also, small amounts of acetic acid are found in these feedstuffs. Fermentation products should be accounted for in the calculation of the energy value of such feedstuffs. Because the level of acetic acid is very low, the amount of acetic acid is added to the lactic acid content. The metabolizable energy value of lactic acid is derived from the ATP-yielding capacity of lactic acid compared to starch. This results in a MEbr value for lactic acid of 14.55 MJ/kg.

5.2.2.3.4 New MEbr equation

From the above, a new equation for the calculation of MEbr was derived:

[F.P23] MEbr (MJ/kg) = (18.03*DCP + 38.83*DCFATh + 17.32*D(STA+SUG) + 14.72*LA) / 1000

Or:

[F.P24] MEbr (kcal/kg) = 4.31*DCP + 9.28*DCFATh + 4.14*D(STA+SUG) + 3.52*LA

(with contents of DCP, DCFATh. V(STA+SUG) and LA in g/kg)

5.2.2.4 Calculation rules for calculating DCP, DCFATh and D(STA+SUG)

For all feedstuffs – for which a MEbr value for broilers is given – equations have been developed for the calculation of the required contents of fecal digestible components DCP, DCFATh and D(STA+SUG). The estimation equations are - for most feedstuffs - derived from statistical analysis (regression analysis) of datasets containing digestibility trials of individual feedstuffs, or combined datasets containing data of comparable feedstuffs. For some feedstuffs, insufficient or no digestibility trials were available to perform statistical analysis. In those cases, the digestibility was based on the mean values from one or a limited number of observation(s). For some feedstuffs – rarely used in poultry diets, and for which no digestibility trials were available – the

digestibility was estimated by comparing the chemical composition and other characteristics of that feedstuff to comparable feedstuffs of which sufficient digestibility data with broilers were available. These detailed calculation rules are not provided in the Feed Table, but have been included – together with other calculation rules for feed evaluation of poultry – in a separate CVB publication, entitled 'CVB Calculation Rules Feed Evaluation Systems Poultry 2011' (Documentation report no 57).
In developing the estimation equations, it was always investigated which other components affect the digestibility of a certain component. In developing equations for digestible crude protein (DCP), also a basal endogenous faecal excretion of 9.7 g CP per kg DMI was always accounted for.

Dividing the digestible contents (e.g., DCP) – as calculated by means of the above-mentioned product-specific calculation rules – by the gross nutrient content, and subsequently multiplying by 100 (e.g., DCP/CP*100), the digestibility coefficient of that nutrient (e.g., DCCP) is obtained. On the product sheets, the digestibility coefficients for CP, CFAT and (STA+SUG) is given, belonging to the average chemical composition as also stated on the product sheet. For batches with a deviant composition, this digestibility coefficient is not entirely correct; in those cases, the digestibility coefficient is better estimated by using the specific calculation rules for that product.

The digestibility of pure fats is strongly dependent on the fatty acid composition. Based on a study, commissioned by the CVB, it appeared that the digestibility of fat (DCCFAT) could be predicted well with the following formula:

[F.P25] DCCFAT (%) = 96.1 – 0.3746 * (C16:0 + C18:0)

With (C16:0 + C18:0) in percent units of the total fatty acid fraction

For animal products (meat meal, fish meal) it is assumed that the NFEh fraction is largely an artefact. Many times negative values are calculated for the NFEh fraction. These negative values for NFEh can be the result of converting an analysed nitrogen content to a CP value (CP = 6.25 * N) as this conversion value of 6.25 may not be correct. In all evaluation systems in which the NFEh fraction is used for calculating energy values it is assumed that the DCNFEh of animal products is equal to the DCCP value. In the updated MEbr system a basal fecal endogenous loss of CP is assumed of 9.7 g per kg DM. Therefore it is not correct to use the the DCCP value of animal products also as a value for DCNFEh because in that case the calculated basal fecal endogenou CP loss is used twice in the same feed. Therefore, for broilers the following calculation rule is used. First a combined DCP and DNFEh fraction is estimated: (DCP + DNFEh) = a*(CP + NFEh) – 9.7 (all values expressed in DM and where a = the standardized digestibility of the animal product). Then the combined DC(CP + NFEh) is calculated: DC(CP + NFEh) = (DCP + DNFEh) / (CP + NFEh) * 100. This means that the value for DCCP for animal products is the value for DC(CP + NFEh).

5.3 Protein value for poultry

5.3.1 Feedstuffs

In 2017 two CVB documentation reports (CVB documentation reports nr. 60 and 61) were published. In CVB documentation report nr. 60 the amount and amino acid composition of basal endogenous losses at the terminal ileum of broilers were estimated based on a meta-analysis on a large number of published scientific studies. In CVB documentation report nr. 61 a Table is published with standardized ileal digestible amino acid coefficients for a wide range of feedstuffs for poultry. This Table is based on 1) a large dataset of published studies in which amino acid digestibilities for a large number of feedstuffs for poultry were determined and 2) on the in CVB documentation report nr. 60 established amount and amino acid composition of basal endogenous losses at the terminal ileum of broilers.

These standardized ileal digestible amino acid coefficient values for a wide range of feedstuffs for poultry are presented in this Table and replace the apparent fecal digestibility amino acid values of feedstuffs for poultry that were shown in the CVB Feed Tables since 1979.

Synthetic amino acids
When synthetic amino acids are added to a compound feed, these substances may be regarded as fully digestible. Just as for feedstuffs that do not contain protein the basal ileal loss of amino acids is not taken into account.
Furthermore, synthetic amino acids are sometimes sold in the form of salts. Even if these salts have a high degree of purity, it should be taken into account that they do not consist entirely of the amino acid concerned. Therefore, one should proceed from the content of the amino acid, as guaranteed by the producer.

5.4 Digestibility of phosphorus

In 1997 the system “Digestible phosphorus for poultry” has been implemented (CVB, 1997). The P-digestibility of feedstuffs for poultry is based on research done by ID-DLO (now part of the Animal Sciences Group, Lelystad), measuring the absorption coefficient in broilers under standard conditions (a balance period between days 21 and 24 of age, fed a semi-synthetic diet with an (estimated) digestible P (DPpo) content of 1.8 g/kg and a Ca content of 5.0 g/kg). With this marginal DPpo content the P supply is so low that the P excretion via the urine is negligible and all excreted P is (apparently) not absorbed P from the feed.

From the research done by ID-DLO it was determined that broilers are capable of (partially) releasing P from inositol phosphate present in feedstuffs of vegetable origin. Furthermore, it was established that this breakdown depends on the DPpo (and Ca) level in the feed; this implies that a correction is needed to convert the P digestibility values as measured under standardized conditions (DPpo) into P digestibility values for practical conditions (diets containing 3.0 DPpo/kg and 6.8 g Ca/kg) (cDPpo). For this correction, relationships are applied that have been derived from ID-DLO research, where the faecal P digestibility under standard conditions was compared to the ileal P digestibility at practical DPpo and Ca levels for eight feedstuffs (CVB, 1997). For feedstuffs of animal origin and for feed phosphates, such a correction is not needed.

The (c)DPpo values given in this Table have all been based on research by ID-DLO. Feedstuffs of vegetable and of animal origin, as well as feed phosphates were included in this study. For a number of feedstuffs, little to no observations concerning the P digestibility are known. In those cases, the P digestibility was derived from related feed ingedients, or was estimated. The estimation was based on an P digestibility value for non-inositol-bound P of 80% and usually a low breakdown of inositol-phosphate was assumed.
Information on feed phosphates is included in this Table in a separate Appendix. In general, a distinction is made between mono- and dicalcium phosphates (water containing or dry), and other feed phosphates.
Some feedstuffs of vegetable origin contain considerable amounts of the enzyme phytase, which is capable of (partially) releasing P from inositol phosphate. This may have a favourable effect on the P digestibility of these feedstuffs. One should, however, take into account the temperature sensitivity and pH dependency of the enzyme. Steam pelleting, leading to pellet temperatures above 80 ^{o}C, causes the endogenous phytase activity to drop dramatically.

The table values are based on the assumption that no phytase is present in the feedstuff. This approach is of interest for barley, rye, rye products, wheat, wheat by-products and triticale. The P digestibility values that apply when these products are offered without prior heat pelleting processes are given in a section ‘Points of attention’, given after the product sheets for compound feedstuffs.
Although the P digestibility values are based on broiler research, they are also applied for other types of poultry. In the case of laying hens, comparative research is the foundation for the application of these values and for the determination of requirements.

Concerning P requirements, refer to the CVB Documentation report no 20, where the final digestible P system is described (CVB, 1997).

On the product sheets, the content of digestible phosphorus (DPpo) is stated in the column “Roosters/Laying hens”; this value is of course also applicable for broilers.

5.5 Calculation examples

For calculation examples, with step-wise explanation of the calculation of the feeding values within the various systems for poultry, see document RD008 on the CVB website: www.cvbdiervoeding.nl.

6. FEED EVALUATION SYSTEM FOR RABBITS

6.1 Feed evaluation for rabbits

For the energy evaluation of feedstuffs for rabbits, in the past different systems have been used, derived from evaluation systems for ruminants, pigs, or poultry. Research has shown, however, that none of these systems can predict the relative proportion in energy values for rabbits in a reliable way.
In 1988, the then ACV (Stichting Afnemers Controle op Veevoeder) took the initiative to develop a separate feeding values table for rabbits. Thanks to the cooperation of the then COVP-DLO (now part of the Animal Sciences Group, Lelystad), the then Rijksstation voor Kleinveeteelt in Merelbeke, België (now part of the Institute for Agricultural and Fisheries Research, ILVO, Belgium) and the Dutch compound feed industry (Janssen et al., 1990), this has led to a preliminary OE Table Rabbits in 1990 (CVB, 1990). Thereafter, this table has been incorporated in the CVB Feedstuff Table.

6.2 Energy value

6.2.1 Digestibility figures

In eighties of the 20th century, the Rijksstation voor Kleinveeteelt (Merelbeke, Belgium) has performed many studies on the feeding value of feedstuffs for rabbits. These values were usually implemented. Apart from the data provided by the Rijksstation voor Kleinveeteelt, information in literature was scarce. The stated values on digestibility of crude fat are approximations, based on fat extraction with petroleum ether after acid hydrolysis (feed ingredient and faeces). Some values derived from the Rijksstation voor Kleinveeteelt had to be adjusted accordingly.

6.2.2 Energy evaluation system

At first, an energy evaluation system for rabbits was chosen that had been developed by dr ir L. Maertens of the Rijksstation voor Kleinveeteelt. This system is based on the apparent digestibility of nutrients (apparent digestible energy rabbits, ADEr). The equation below has in fact been developed for compound feeds, but has later been accepted for the calculation of the energy value of raw materials.

[F.K.01] ADEr (MJ) = (23.85 x DCP + 37.8 x DCFAT + 16.3 x DCF + 17.1 x DNFE) / 1000

The value of protein is overestimated in this system: the factor 23.85 MJ per kg DCP assumes that all digestible amino acids are deposited in body protein. In reality, the digested protein is only partly (30-50%) deposited in body protein, while the remaining nitrogen is excreted via the urine, mainly as urea. The digestible energy, corrected for N balance, may be calculated using the following equation:

[F.K.02] OEk (MJ) = (19.0 x DCP + 37.8 x DCFAT + 16.3 x DCF + 17.1 x DNFE)/1000
OEk in MJ/kg; the contents of DCP, DCFAT, DCF and DNFE in g per kg

This equation was used to calculate the energy value of feedstuffs in this Table.

Only for alfalfa meal or pellets it proved possible to derive a reliable relation between variation in chemical composition and nutrient digestibility. This equation is also used for grass meal or pellets.
For the other feedstuffs, it was not possible to relate quality and chemical composition on the one hand, and nutrient digestibility on the other hand. For the relevant by-products of maize and

wheat, the digestibilities of nutrients have been related to the crude fibre content (based on a limited amount of data), as has been done for other animal species. For various feedstuffs no digestibility figures have been determined using rabbits. In those cases, estimated values are given, by comparison with related feedstuffs and/or other animal species.

6.3 Calculation examples

For calculation examples, with step-wise explanation of the calculation of the feeding values for rabbits, see document RD009 on the CVB website: www.cvbdiervoeding.nl.

7. FEED EVALUATION SYSTEM FOR HORSES

7.1 Feed evaluation systems

In the past, the feed evaluation system for horses was based on the VEM and DCP system for ruminants. In 1996, two evaluation systems were developed especially for horses: the VEP system (a net energy evaluation system, with VEP 'Voedereenheid Paarden' as characteristic) and the DCPh system (a protein evaluation system: DCPh = digestible crude protein horses). These systems were developed based on the French UFC system.
In September 2004, the VEP system was replaced by a new net energy system, the EWpa (= Energy value Horses). The feed evaluation within this system has also been derived from the French UFC system. From January 1st 2005, the EWpa system has officially been implemented. For a full explanation of the EWpa system and the (partly revised) DCPh system, the reader is referred to CVB Documentation report no 31 `The EWpa system and the DCPh system` (CVB, 2004a). From edition 2005 of the Feed Table onwards, the feed evaluation for horses has been incorporated according to these systems, as described in this publication, and in CVB series no 28 (CVB, 2004b).

7.2 Energy value

The EWpa is derived as follows:

7.2.1 Gross energy (GE)

The gross energy content of all feedstuffs is estimated according to the equation from the VEM system (CVB, 1994):

[FE.01] GE (kJ/kg DM) = 24.14*CP + 36.57*CFAT + 20.92*CF + 16.99*NFE – 0.63*SUG*

* The subtraction for sugars only applies to feedstuffs with more than 80 g sugars per kg DM. CP, CFAT, CF, NFE and SUG are expressed in g/kg DM

For fodder maize a separate calculation applies:

[FE.02] GE (kJ/kg DM) = 19456 – 19.456*ASH

In which ASH is expressed in g/kg DM

7.2.2 Digestible energy (DE)

The equations for calculating the digestible energy content are as follows:

- Forages

[FE.03] DE (kJ/kg DM) = (0.034 – 1.1 + 0.9477*DCOM) / 100*GE

- Concentrates

[FE.04] DE (kJ/kg DM) = (0.034 + 1.1 + 0.9477*DCOM) / 100*GE

In which DCOM = digestibility coefficient of organic matter for horses (in %)

During the development of the EWpa system, a critical evaluation has taken place with respect to

the digestibility coefficients of organic matter for horses (%dOMh) that were obtained.
For feedstuffs with known OM digestibility – obtained from digestibility studies with horses – the *in vivo* established %dOMh was used to calculate the digestibility of gross energy. This concerns lucerne (alfalfa), red clover, and some compound feedstuffs.

The existing equation from the VEP system (CVB Documentation report no 15, 1996) was used by CVB internally as an aid to estimate the %dOMh of wheat and wheat byproducts.

During re-evaluation of the existing database, new estimation equations were developed within the EWpa system to estimate the %dOMh of lucerne (alfalfa) and for artificially dried grass, based on chemical parameters:

- Lucerne (alfalfa) (fresh, silage, hay)

[FE.05] DCOM (%) = 98.5 – 0.123*CF (CF in g/kg DM)

- Artificially dried grass and lucerne (alfalfa) (mash, pellets, and pressed in bales)

[FE.06] DCOM (%) = 82.1 – 0.087*CF (CF in g/kg DM)

For a number of feedstuffs or groups of feedstuffs, however, insufficient digestibility trials with horses have been performed to follow this procedure. In those cases, the digestibility of the organic matter was estimated based either on results of digestibility trials with wethers or pigs (see below), or by comparison of the feedstuff with similar feedstuffs.
For the estimation of DCOM from wether data, the following equation for fresh grass and hay has been developed, based on results from digestibility trials with wethers and horses in the Netherlands and France:

[FE.07] DCOM (%) = -16.71 + 1.1436*DCOMw

In which: DCOMw = digestibility coefficient of organic matter for wethers (%)

This equation is used to estimate DCOM for fresh grass and hay, because the equation has been derived from these feedstuffs, but also for grass silage.

By comparing the outcome of this equation to the available data on digestibility of fodder maize for horses, the following equation has been derived for fodder maize (fresh and ensiled):

[FE.08] DCOM (%) = -12.27 + 1.1436*DCOMw

In drafting the feedstuffs table, equation [FE.07] was also applied for a number of products with unknown DCOM, but with a known DCOMw. In this respect, however, there is a difference with the previous VEP system: in the VEP system, this equation was used for all feedstuffs with unknown *in vivo* determined DCOM, but known DCOMw. In the EWpa system, care was exercised in applying equation [FE.05] in those cases where the chemical composition of the feedstuff differed markedly from that of fresh grass and grass hay. In each case, the calculated value of DCOM was compared with the DCOMw (the basis for the calculation), and with the DCOMp (= digestibility coefficient of organic matter for pigs). In cases where this comparison led to the conclusion that the calculated DCOM did not yield a logical value, the DCOMw and the DCOMp were regarded as more valuable than the outcome of equation [FE.07].

In Tables 2 and 3 (Chapter 5), a '*' sign is used to indicate that the stated coefficients have not been established with horses, and the stated value should be regarded as indicative.

7.2.3 Metabolisable energy (ME)

Metabolisable energy is digestible energy minus energy lost through methane and urine. The extent of these losses is affected by the composition of the ration, the crude fibre content of the

diet, and the protein content.
For all feedstuffs, the following equation applies:

[FE.09] ME (kJ/kg DM) = DE * (93.96 – 0.02356*CF – 0.0217*CP) / 100

In which CP and CF are expressed in g/kg DM

7.2.4 Utilization of metabolizable energy for maintenance (k_m)

Part of metabolizable energy is still lost. The required energy for feed intake and heat production caused by feed consumption and processing do not benefit the maintenance or production of the animal. The value of k_m (the proportion of ME that is used for maintenance processes) depends on the endproducts of digestion.
The method of calculation of k_m varies depending on the product group. For products that may not be placed in a certain group, and for groups containing only a limited number of feedstuffs, a k_m value is estimated based on the k_m of comparable products, and/or based on the k_m value in other animal species.
Equations [FE.15] and [FE.16] were not derived from the UFC system. Equation [FE.15] is added to prevent undervaluation of pure fats.

Forages
[FE.10] k_m = (65.21 – 0.0178*CF + 0.0181*CP + 0.0452*(STA+SUG)) / 100

Cereal grains and seeds
[FE.11] k_m = (72.34 + 0.0119*CF – 0.0081*CP + 0.0112*(STA+SUG)) / 100

Cereal byproducts
[FE.12] k_m= (94.41 – 0.0237*OM – 0.0022*CP + 0.0121*(STA+SUG)) / 100

Byproducts from oil processing (1): peanut products, cottonseed products, coconut products, palm kernel products, sunflower seed products
[FE.13] k_m = (67.03 – 0.004261*CP + 0.01566*(STA+SUG)) / 100

Byproducts from oil processing (2): linseed products, rapeseed products, soy products
[FE.14] k_m = (68.04 – 0.004261*CP + 0.01566*SUG) / 100

Fats of animal and vegetal origin
[FE.15] k_m = 0.80

Glucose, saccharose, starch
[FE.16] k_m = 0.85

In which all contents are expressed in gram per kg DM

When an equation contains STA, the STAam content (in g/kg DM) should be used. The calculated k_m may be very high for products containing large amounts of sugars or starch, therefore, it was decided to set a maximum value for k_m of 0.85, the same value as for glucose and lactic acid.

7.2.5 Net energy for maintenance (NEm)

Multiplying the calculated ME by the calculated k_m yields the net energy of the feedstuff: NE = ME * k_m.

During the development of the VEP system it appeared that fat-rich feedstuffs were underestimated in the UFC system. Incorporating the ME of CFAT with a k_m of 0.80 (instead of

the k_m calculated for the complete feedstuff) gives a better valuation of CFAT. The ME content of CFAT is calculated as follows:

MEcfat = GEcfat * %dEcfat * ME/DEcfat = 36.6 * 0.9 * 0.95 = 31.3 kJ

The equation for calculating NEm, therefore, becomes:

[FE.17] NEm (MJ/kg DM) = (k_m * (ME – 31.3*CFAT) + 0.80*31.3*CFAT) / 1000

In which: k_m = the k_m for the complete feedstuff
ME = the calculated ME content of the feedstuff in kJ/kg DM
CFAT = the CFAT content of the feedstuff in g/kg DM

Equation [FE.17] is applied to all feedstuffs, with the exception of vegetable and animal fat; for these feedstuffs a fixed k_m (0.80) is applied as follows:

[FE.18] NEm (MJ/kg DM) = (0.80 * ME)/1000

In accordance with the approach taken in the VEM system and EW system for ruminants and pigs, respectively, this net energy value is calculated - for application in practice - to an energy value for horses (EWpa). EWpa is calculated with the energy value of oats as a reference. One kg of oats of average quality contains 8.93 MJ NEm per kg DM. The EWpa of 1 kg oats dry matter is set to 1.000. The EWpa of any given feedstuff is then derived as follows:

[FE.19] EWpa (per kg DM) = NEm / 8.93

In which: NEm = Net Energy in the feedstuff (in MJ/kg DM)
8.93 = Net Energy in 1 kg oats dry matter of average quality (in MJ/kg DM)

Because all calculations are performed with contents in the DM, the outcome of equation [FE.19] should be corrected with the DM content of the product, to yield the EWpa per kg of product:

[FE.20] EWpa (per kg product) = EWpa (per kg DM) * DM/1000

In which DM = dry matter content of the product (in g/kg)

7.2.6 How to calculate EWpa

In contrast with the feeding value calculation for other aninal species in the Feed Table, the equation code stated with the horses data does not refer to one single equation, but to a series of equations that are applied subsequently. The Table below represents the various calculation methods, as shown on the separate product sheets. For each group of products, it is stated which equations have been used to calculate values for GE ([FE.01] or [FE.02]), DE ([FE.03] or [FE.04]), k_m ([FE.10] until [FE.16]), and NEm ([FE.17] or [FE.18]). The following calculation steps are the same for all feedstuffs: for the calculation of the ME/DE ratio ([FE.09]), the conversion from NEm (in DM) to EWpa (in DM) ([FE.19]), and the conversion fo the EWpa in DM to EWpa on product basis ([FE.20]). The various combinations of formulas used to calculate EWpa are shown in Table 1.

Table 1 Overview of equations used to calculate EWpa

Calculation method	GE	DE	ME/DE	k_m	NEm	NEm -> EWpa	EWpa (DM) -> EWpa (product)
1	FE.01	FE.03	FE.9	FE.10	FE.17	FE.19	FE.20
2	FE.01	FE.04	FE.9	FE.11	FE.17	FE.19	FE.20
3	FE.01	FE.04	FE.9	FE.12	FE.17	FE.19	FE.20
4	FE.01	FE.04	FE.9	FE.13	FE.17	FE.19	FE.20
5	FE.01	FE.04	FE.9	FE.14	FE.17	FE.19	FE.20
6	FE.02	FE.03	FE.9	FE.10	FE.17	FE.19	FE.20
7	FE.01	FE.04	FE.9	FE.15	FE.17	FE.19	FE.20
8	FE.01	FE.04	FE.9	FE.16	FE.17	FE.19	FE.20

7.3 Protein value

INRA took the digestive physiology of the horse as starting point for their protein evaluation system. However, available base data to develop this system are very scarce and many assumptions were made. Therefore, it was decided not to adopt the French MADC system.
For the time being, the DCP system will remain in place to estimate the protein value of feedstuffs for horses. In cases where data were available on the digestibility of crude protein for horses, these values were used to calculate DCP. In other cases, the %dCP was derived from the CP digestibility for ruminants and pigs.
For all feedstuffs the following applies:

[FE.21] DCP (in g/kg DM) = CP * DCCP/100 (in g/kg DM)

In which: CP is expressed in g/kg DM
DCCP is expressed in %

7.4 Calculation examples

For calculation examples, with step-wise explanation of the calculation of the feeding values for horses, see document RD010 on the CVB website: www.cvbdiervoeding.nl.

9. LIST OF ABBREVIATIONS

Abbreviation	Unit	Description
%DASH	%	Digestibility of Crude Ash
%DRUP	%	Intestinal digestibility of rumen undegraded dietary protein
%FA	%	Percentage of a certain fatty acid in total fatty acids
%RUP	%	Undegradability of dietary protein; percentage rumen undegraded protein
%RUSTA	%	Undegradability of starch; percentage rumen undegraded starch
%StaiDC	%	Standardized ileal digestibility coefficient
<=C10	g	Fatty acids with 10 C atoms or less
>=C20	g	Fatty acids with 20 C atoms or more
AA	g	Amino acid(s)
AC	g	Acetic acid
ADEr		Apparent digestible energy rabbits
ADF	g	Acid detergent fibre
ADL	g	Acid detergent lignin
ALA	g	Alanine
ANF		Antinutritional factor(s)
APL		Animal production level
ARG	g	Arginine
ASH	g	Crude ash
ASP	g	Aspartic acid
ATP	mol	Adenosine triphosphate
BU	g	Butyric acid
BW	kg	Body weight
$BW^{0.75}$	kg	Metabolic body weight
C12:0	g	Lauric acid
C14:0	g	Myristic acid
C16:0	g	Palmitic acid
C16:1	g	Palmitoleic acid
C18:0	g	Stearic acid
C18:1	g	Oleic acid
C18:2	g	Linolic acid
C18:3	g	Linolenic acid
Ca	g	Calcium
CAD	meq/kg	Cation-anion difference
cDPpo		Corrected digestible Phosphorus poultry
CF	g	Crude fibre
CF_DI		Correction factor for disaccharides
CFAT	g	Crude fat
CFATh	g	Crude fat after acid hydrolysis

Abbreviation	Unit	Description
Cl	g	Chlorine
Co	g	Cobalt
CP	g	Crude protein
Cu	g	Copper
CYS	g	Cystine
D	%	Potentially degradable fraction
DASH	g	Digestible ash
DC	%	Digestibility Coefficient
DCCF	%	Digestibility of Crude Fibre
DCCFAT	%	Digestibility of Crude Fat
DCCFATh	%	Digestibility of Crude Fat after acid hydrolisis
DCCP	%	Digestibility of Crude Protein
DCCPh	%	Digestibility of Crude Protein in horses
DCiSTA	%	Ileal Digestibility of STAam
DCNFE	%	Digestibility of NFE
DCNFEh	%	Digestibility of NFEh
DCOM	%	Digestibility of Organic Matter
DCOMp	%	Digestibility of Organic Matter for pigs
DCOMw	%	Digestibility of Organic Matter for wethers
DCPpi	%	Digestibility of P (Phosphorus) in pigs
DCPpo	%	Digestibility of P (Phosphorus) in poultry
DC(S+S)	%	Digestibility of (STAam + SUG)
DE	MJ	Digestible energy
DM	g	Dry matter
DMCP		Intestinal degradable microbial crude protein
DMFLYS		Lysine contribution from DMFP
DMFMET		Methionine contribution from DMFP
DMFP	g	Intestinal digestible metabolic faecal protein; that part of DVE that is lost in endogenous faecal protein
DMI	kg	Dry matter intake
DMLYS		Lysine contribution from DMP
DMMET		Methionine contribution from DMP
DMP	g	Intestinal digestible microbial protein; (part of DVE)
DMSO		Dimethyl Sulphoxide
DPpi	g	(Faecal) digestible Phosphorus in pigs
DPpo	g	(Faecal) digestible Phosphorus in poultry
DRULYS		Lysine contribution from DRUP
DRUMET		Methionine contribution from DRUP
DVE	g	DarmVerteerbaar Eiwit; intestinal digestible protein
DVLYS	g	DarmVerteerbaar Lysine; Intestinal digestible lysine
DVMET	g	DarmVerteerbaar Methionine; Intestinal digestible methionine
EB	meq/kg	Electrolyte Balance
ETH	g	Ethanol
EW		Energy value pigs = NEv (in MJ) / 8.8 MJ

Abbreviation	Unit	Description
EW_{2015}		Energy value pigs = NE_{2015} (in MJ) / 8.8 MJ
EWpa		Energy value horses = NEm (in MJ) / 8.93 MJ
FA		Fatty acids
Fe	g	Iron
FCH	g	Fermentative degradable carbohydrates
FIC		Feed intake capacity
FOM	g	Fermentable Organic Matter (Calculated from DOM, from which rumen undegraded protein, rumen undegraded starch and crude fat are subtracted)
FOMr	g	Fermentable organic matter in the rumen (Based on the quantification of rumen fermentable components from *in situ* experiments)
FOMr2	g	Organic matter that is fermented in the rumen during the first two hours in the rumen
FOMr2/FOMr	g	Ratio between FOMr2 and FOMr
FSTA	g	Fermentable starch (= STA - RUSTA)
FP	g	Fermentation products (LA+AC+PR+BU)
FTU		Phytase units
g		Gram
GE	MJ	Gross energy
GLU	g	Glutamic acid
GLY	g	Glycine
GOS	g	Glucose oligosaccharides
HIS	g	Histidine
HPLC		High performance liquid chromatography
iDM	g	Indigestible dry matter
iDMI		Indigestible dry matter intake
ILE	g	Isoleucine
IP	g	Inositol bound phosphorus
IP/P	%	Inositol bound phosporus as a percentage of total phosphorus
IV		Iodine value
J	g	Iodine
K	g	Potassium
kcal		Kilocalories
k_f		ME-utilization for energy growth
kg		Kilogram
kJ		Kilojoule
k_m		ME-utilization for maintenance
LA	g	Lactic acid
LAB		Liquid associated bacteria
LEU	g	Leucine
LYS	g	Lysine
MCPe		Microbial CP produced, based on the available energy in the rumen
MCPn		Microbial CP produced, based on available nitrogen in the rumen
MDASH	g	Maximal amount of digestible crude ash
ME	MJ / kcal	Metabolizable energy

Abbreviation	Unit	Description
MEbr	MJ / kcal	Metabolizable energy for broilers
MEla	MJ / kcal	Metabolizable energy for laying hens
MEpo	MJ / kcal	Metabolizable energy for poultry
meq		milli equivalents
MET	g	Methionine
MFP		Metabolic faecal protein
mg		Milligram
Mg	g	Magnesium
MJ		Megajoule
Mn	g	Manganese
Mo	g	Molybdeen
N	g	Nitrogen
Na	g	Sodium
NDADF		ADF content in NDF
NDF	g	Neutral detergent fibre
NE	MJ	Net energy
NE_{lac}	MJ	Net energy value for milk production
NE_{meat}	MJ	Net energy value for meat production
NEm	MJ	Net energy value for maintenance
NEv	MJ	Net energy value for fat accretion in pigs
NE_{2015}	MJ	Net energy value for pigs for growth; introduced in 2015
NFE	g	N-free extracts, with CFAT subtracted (so: 1000 – (moisture + ASH + CP + CFAT + CF)
NFEh	g	N-free extracts, with CFATh subtracted
NPN	g	Non protein nitrogen
NSP	g	Non starch polysaccharides = 1000 – (moisture + ASH + CP + CFAT + STAam + GOS + CF_DI*SUG + 0.92*LA + 0.5*(AC+PR+BU) + GLYCEROL)
NSPh	g	Non starch polysaccharides = 1000 – (moisture + ASH + CP + CFATh + STAam + GOS + CF_DI*SUG + 0.92*LA + 0.5*(AC+PR+BU) + GLYCEROL)
OEB	g	Onbestendig Eiwit Balans; rumen degraded protein balance
OEB-2	g	OEB two hours after feed intake
OEk		Metabolisable energy for rabbits
OM	g	Organic matter
P	g	Phosphorus
PAB		Particle associated bacteria
PDV		Product Board Animal Feed
PHE	g	Phenylalanine
PR	g	Propionic acid
PRO	g	Proline
q		%ME in GE
RNSP	9	Remainder NSP fraction, after subtracting NDF from NSP (RNSP = NSP – NDF)
RNSPh	9	Remainder NSPh fraction, after subtracting NDF from NSPh (RNSP = NSPh – NDF)

Abbreviation	Unit	Description
RUP	g	Rumen undegraded dietary protein
RUSTA	g	Rumen undegraded starch
S	g	Sulphur
S	%	Soluble fraction
sd		Standard deviation
sdc		Corrected standard deviation
SER	g	Serine
S-i	g	Inorganic sulphur
S-o	g	Organic sulphur
STA		Starch
STAam	g	Starch determined by amyloglucosidase
STAam-e	g	Enzymatically digestible starch
STAam-f	g	Fermentable degradable starch
STAew	g	Starch determined according to Ewers
STAtot	g	STAam plus GOS
SUG	g	Sugars
SUGe	g	Enzymatically digestible sugars
SUGe/SUG	%	Ratio indicating which percentage of the total SUG content consists of enzymatically digestible SUG
SUGf	g	Fermentable degradable sugars (= SUG – SUGe)
SW		Structuurwaarde; Structure Unit
TDMI		Total dry matter intake
THR	g	Threonine
TRP	g	Tryptofaan
TYR	g	Tyrosine
U	%	Undegradable fraction
$uCP_{i\text{-}basal}$	g/kg	Amount of undigested basal endogenous protein (expressed as g/kg ingested feed) at the end of ileum
$uCP_{i\text{-}endogenous}$		Total amount of undigested endogenous protein that passes the ileum
$uCP_{i\text{-}specific}$		Amount of undigested endogenous protein (g/kg feed), induced by feed specific factors, at the end of the ileum
VAL	g	Valine
VEM		Voedereenheden voor melkproductie; Feed unit milk production
VEVI		Voedereenheden voor vleesproductie; Feed unit meat production
VFA		Volatile fatty acids (sum of Ac, Pr and Bu)
VW		VerzadigingsWaarde; Fill Unit
W	%	Washable fraction
Zn	g	Zinc

10. CHEMICAL COMPOSITION AND FEEDING VALUES OF FEEDSTUFFS

In this chapter information is given for the following categories of feedstuffs:

10.1 Compound feedstuffs
10.2 High moisture industrial co-products
10.3 Roughages and related products
10.4 Mineral feedstuffs
10.5 Miscellaneous

Compound feedstuffs

Remarks

Grass meal-CP < 140 g/kg:

1. This product may be contaminated with sand / soil; this is the case when the ASH content is higher than approximately 75 g/kg DM.

2. The content of sugar may vary considerably, depending on conditions for growth and harvesting.

3. The botanical composition of this product class mostly differs from the other classes. therefore, for this class the values of VEM and VEVI are calculated differently from the other classes.

Grass meal-CP 160 - 200 g/kg:

1. This product may be contaminated with sand / soil; this is the case when the ASH content is higher than approximately 75 g/kg DM.
2. The content of sugar may vary considerably, depending on conditions for growth and harvesting.
3. In calculating the feeding value for ruminants the cutting date is assumed to be first of July (day 91).

Remarks

Linseed:

1. The DCCFATh for pigs only applies for linseed that has been grinded very well so that the structure of all fat cells is destroyed so that the fat inside the cells can be digested well.

Linseed expeller 3006.401/0/0

Remarks

Lucerne (alfalfa) meal-CP < 140 g/kg:

1. This product may be contaminated with sand / soil; this is the case when the ASH content is higher than approximately 85 g/kg DM.
2. This product is usually naturally dried (sun-cured).
3. The feeding value for ruminants is calculated without an adjustment for cutting date.

Lucerne (alfalfa) meal-CP 140 - 160 g/kg 5004.610/2/0

Remarks

Maize germs-STAew < 200 g/kg:

1. The DCCFATh for pigs only applies for the situation when the fat has been made very well accessible to lipases by means of thorough grinding and pelleting.

Maize germs-STAew > 200 g/kg 1002.102/2/0

Remarks

Milk powder, whole:

1. SUG is represented as glucose units. Lactose = 0.95 * SUG.
2. SUGe/SUG for pigs only applies when lactose containing diets are fed on a regular basis; otherwise SUGe/SUG = 0.
3. For the digestibility of the NFE fraction in poultry complete fermentation of lactose (present in limited amounts in the diet) is assumed.

Milkpowder, skimmed 8008.000/0/0

Remarks

Milkpowder, skimmed:

1. SUG is represented as glucose units. Lactose = 0.95 * SUG.
2. SUGe/SUG for pigs only applies when lactose containing diets are fed on a regular basis; otherwise SUGe/SUG = 0.
3. For the digestibility of the NFE fraction in poultry complete fermentation of lactose (present in limited amounts in the diet) is assumed.
4. Nutrient contents and feeding values in denaturated skimmed milk powder can be calculated from the mixing ratios of skimmed milk powder and the substance used for the denaturation process.

Remarks

Processed animal protein, Dutch origin:

1. Processing this product in feeds for pigs, poultry and ruminants is not allowed (EC No 999/2001).
2. The content of linoleic acid may vary from 3 to 12%.
3. The ASH content differs per supplier, the concentration of minerals varies accordingly.

Processed animal protein, European origin-CFATh < 100 g/kg
8001.001/1/0

Remarks

Processed animal protein, European origin-CFATh > 100 g/kg:

1. Processing this product in feeds for pigs, poultry and ruminants is not allowed (EC No 999/2001).
2. The content of linoleic acid may vary from 3 to 12%.

Remarks

Rape seed:

1. The content of S-o does not include the sulphur bound to thioglucosinolates.
2. The nutrient digestibility values mentioned for pigs and poultry apply to the so-called double-zero variety.
3. The DCCFATh for pigs only applies for rapeseed that has been grinded very well so that the structure of all fat cells is destroyed so that the fat inside the cells can be digested well.
4. The DCCFATh of 84% for broilers is applicable only for rapeseed that has been grinded very well; if this is not the case a DCCFATh of 78% is advised.

Remarks

Rape seed meal, solvent extracted-CP < 370 g/kg:

1. The content of S-o does not include the sulphur bound to thioglucosinolates.
2. The nutrient digestibility values mentioned for pigs and poultry apply to the so-called double-zero variety.

Rape seed meal, solvent extracted-CP > 370 g/kg 3009.407/2/0

Remarks

Rape seed meal, solvent extracted-CP > 370 g/kg:

1. Sometimes mustardseed meal, solvent extracted is traded under this name.
2. The content of S-o does not include the sulphur bound to thioglucosinolates.
3. The nutrient digestibility values mentioned for pigs and poultry apply to the so-called double-zero variety.

Remarks

Sorghum:

1. The digestibility coefficients mentioned for broilers, roosters and laying hens only apply for sorghum containing less than 4 g tannin per kg.

Sorghum gluten meal 1008.204/0/0

Remarks

Soya bean hulls-CF < 320 g/kg:

1. This class contains to some extent pieces of soya beans that may not have been heat treated.

Soya bean hulls-CF 320 - 360 g/kg 3012.505/2/0

Remarks

Soya beans, heat treated:

1. this composition does not apply for dehulled, toasted soya beans.
2. The DCCFATh for pigs only applies for a ground product.
3. The nutrient digestibility values mentioned for roosters and laying hens apply for grounded unpelleted feeds.
4. The DCCFATh for broilers is valid for pelleted feeds.

Soya beans, raw 3012.000/0/0

Remarks

Sugar:

1. The energy value for ruminants has been derived from starch, based on its ATP yielding capacity.
2. SUG is represented as glucose units. The sacharose content is 0.95 * SUG = 1000 g/kg.

Sugarbeet pulp, dried-SUG < 100 g/kg 4004.209/1/0

Remarks

Sugarbeet pulp, dried-SUG < 100 g/kg:

1. Vinasse may be added to this class of sugar beet pulp. In case vinasse is added the K content will be higher than mentioned.
2. The NE2015 and EW2015 have been calculated including an addition for reduced activity.

Sugarbeet pulp, dried-SUG 100 - 150 g/kg 4004.209/2/0

Remarks

Sugarbeet pulp, dried-SUG 100 - 150 g/kg:

1. This class of sugar beet pulp contains molasses.
2. The NE2015 and EW2015 have been calculated including an addition for reduced activity.
3. The AA pattern is based on the relative proportions of sugar beet pulp (SUG < 100 g/kg) and sugar beet molasses, and the AA pattern of these products.

Sugarbeet pulp, dried-SUG 150 - 200 g/kg 4004.209/3/0

Remarks

Sugarbeet pulp, dried-SUG 150 - 200 g/kg:

1. This class of sugar beet pulp contains molasses.
2. The NE2015 and EW2015 have been calculated including an addition for reduced activity.
3. The AA pattern is based on the relative proportions of sugar beet pulp (SUG < 100 g/kg) and sugar beet molasses, and the AA pattern of these products.

Sugarbeet pulp, dried-SUG > 200 g/kg 4004.209/4/0

Remarks

Vinasse, beet-CP < 240 g/kg:

1. The CP fraction contains a substantial amount of NPN that yields no energy. For the NE2015 calculation the DCCP is therefore set at 40%.

2. The S-i content of this product is variable; for a correct calculation of the CAD value of a batch the S-i content should be analysed.

Vinasse, beet-CP > 240 g/kg 4004.306/2/0

Remarks

Whey powder:

1. SUG is represented as glucose units. Lactose = 0.95 * SUG.
2. SUGe/SUG for pigs only applies when lactose containing diets are fed on a regular basis; otherwise SUGe/SUG = 0.
3. For the digestibility of the NFE fraction in poultry complete fermentation of lactose (present in limited amounts in the diet) is assumed.

Whey powder, low lactose-ASH < 210 g/kg 8009.626/1/0

Remarks

Brewer's grains, Meura filter process:

1. This product has a high fermentation rate. Therefore no distinction is made between 'fresh' and 'ensiled'.
2. The NDF content is lower than the analyzed NDF content and is chosen such that RNSP = 0. It is likely that part of the analyzed NDF consists of protein.

Brewer's grains, traditional process-DM < 250 g/kg 1005.313/1/0

Remarks

Brewer's grains, traditional process-DM < 250 g/kg:

1. This product has a high fermentation rate. Therefore no distinction is made between 'fresh' and 'ensiled'.
2. At delivery usually salt is added. The Na-content of the product after salt addition is around 1 g/kg DM and the Cl-content 1.5 g/kg DM.
3. The NDF content is lower than the analyzed NDF content and is chosen such that RNSP = 0. It is likely that part of the analyzed NDF consists of protein.

Brewer's grains, traditional process-DM > 250 g/kg 1005.313/2/0

Remarks

Brewer's yeast, liquid-CP low:

1. Nutrient concentrations are expressed on a DM basis; ethanol is considered part of the dry matter.
2. In reality analysed DM contents will be lower and nutrient values analysed in DM will be higher due to evaporation of ethanol during the drying process.
3. The NSPh fraction is calculated as 1000 - (ASH + CP + CFATh + STAam + GOS + CF_DI * SUG + 0.92 * LA + 0.5 * AC + ETH).
4. Average analysed content (without correction for ETH evaporation) for DM was 99 g/kg and for CP 355 g/kg DM.

Brewer's yeast, liquid-CP average 9001.314/3/0

Remarks

Brewer's yeast, liquid-CP average:

1. Nutrient concentrations are expressed on a DM basis; ethanol is considered part of the dry matter.
2. In reality analysed DM contents will be lower and nutrient values analysed in DM will be higher due to evaporation of ethanol during the drying process.
3. The NSPh fraction is calculated as 1000 - (ASH + CP + CFATh + STAam + GOS + CF_DI * SUG + 0.92 * LA + 0.5 * AC + ETH).
4. Average analysed content (without correction for ETH evaporation) for DM was 103 g/kg and for CP 457 g/kg DM.

Brewer's yeast, liquid-CP high 9001.314/4/0

Remarks

Cheese whey, fresh-CP < 175 g/kg DM:

1. SUG is represented as glucose units. Lactose = 0.95 * SUG.
2. SUGe/SUG for pigs only applies when lactose containing diets are fed on a regular basis; otherwise SUGe/SUG = 0.

Cheese whey, fresh-CP 175 - 275 g/kg DM 8023.000/2/0

Remarks

Cheese whey, fresh-CP 175 - 275 g/kg DM:

1. SUG is represented as glucose units. Lactose = 0.95 * SUG.
2. SUGe/SUG for pigs only applies when lactose containing diets are fed on a regular basis; otherwise SUGe/SUG = 0.

Cheese whey, fresh-CP > 275 g/kg DM 8023.000/3/0

Remarks

Maize gluten feed, fresh and ensiled-STAew < 200 g/kg DM:

1. This product has a high fermentation rate. Therefore no distinction is made between 'fresh' and 'ensiled'.

Maize gluten feed, fresh and ensiled-STAew > 200 g/kg DM 1002.240/2/0

Remarks

Maize gluten feed, fresh and ensiled-STAew > 200 g/kg DM:

1. This product has a high fermentation rate. Therefore no distinction is made between 'fresh' and 'ensiled'.

Maize solubles 1002.212/0/0

Remarks

Potato pulp, pressed, :

1. This product has a high fermentation rate. Therefore no distinction is made between 'fresh' and 'ensiled'.
2. For this product analysis of starch should be based on STAam. STAew is an artefact.
3. The S-i content of this product is variable; for a correct calculation of the CAD value of a batch the S-i content should be analysed.

Potato pulp, pressed, Dutch origin 4001.226/0/0

Remarks

Grass/clover, silage-Red clover:

1. The chemical contents, digestibility coefficients and feeding values are based on 6 batches of grass/red clover mixtures with an average clover percentage of 71%.
2. Training is required in order to make a correct visual assessment of the percentage of clover.

Remarks

Maize silage-DM 300 - 340 g/kg:

1. The nutrient contents of this product sheet are based on NIR analysis results from Eurofins Agro from the period 2015 - 2019.
2. The parameters %RUP and %RUSTA depend on the DM content and the ensiling period. For this product sheet an ensiling period of 90 days is used.
3. After a 327 ensiling period minimum values are reacted for %RUP-1991 (29), %RUP-2007 (41), %RUSTA-1991 (15) en %RUSTA-2007 (18).

Calcium magnesium phosphate $Mg(H_2PO_4)_2$ $Ca(H_2PO_4)_2.H_2O$			100	100	200			84	
Sodium magnesium phosphate; $NaMgPO_4$	131		78	41	173			81[b]	
Magnesium oxide 80 %				480					
Magnesium oxide 72 %				436					

[a]: The mineral composition in this Table is based on the molecular relationships in the pure product.
[b]: This figure is based on only one digestibility trial with a product form one manufacturer.
*: the Ca/P ratio in this product is not constant.
**: Because of the high P contents the standardised and apparent P digestibilities only differ 0.1% from each other. After rounding the values for both parameters the values for both are the same.

10.5 Miscellaneous

10.5.1 Energy values organic acids

10.5.1.1 ATP yielding capacity for organic acids, glucose, sucrose and starch

	Molecular formula	Molecular mass	ATP (mol/mol) Literature based	ATP-yield (Mol/g)	ATP yield relative to starch (%)
Ethanol	C_2H_6O	46	15	0.3261	146.74
Malic acid	$C_4H_6O_5$	134	17	0.1269	57.09
Acetic acid	$C_2H_4O_2$	60	10	0.1667	75.00
Buteric acid	$C_4H_8O_2$	88	27	0.3068	138.07
Citric acid	$C_6H_8O_7$	192	26	0.1354	60.94
Fumaric acid	$C_4H_4O_4$	116	17	0.1466	65.95
Lactic acid	$C_3H_6O_3$	90	17	0.1889	85.00
Propionic acid	$C_3H_6O_2$	74	17	0.2297	103.38
Propylene glycol	$C_3H_8O_2$	76	21	0.2763	124.34
Glycerol	$C_3H_8O_3$	92	20	0.2174	97.83
Glucose	$C_6H_{12}O_6$	180	36	0.2000	90.00
Sucrose	$C_{12}H_{22}O_{11}$	342	72	0.2105	94.74
Starch	$C_6H_{10}O_5$ [1)]	162	36	0.2222 [2)]	100.00

1): The molecular formula represents a glucose unit within starch.

2) The ATP yield is based on an ATP yield of 36 Mol ATP per g of glucose. The earlier Feed Table 2011 had a high ATP yield of 0.2346 Mol per g of glucose and was based on a ATP yield of 38 Mol per Mol of glucose.

10.5.1.2 VEM en VEVI values of organic acids, glucose, sucrose, and starch

	ATP yield relative to starch (%)	VEM	VEVI	ATP loss due to fermentation (%)	VEM	VEVI
		Excluding fermentation loss			Including fermentation loss	
Ethanol	146.74	2385	2759	10	2146	2483
Acetic acid	75.00	1219	1410	0	1219	1410
Buteric acid	138.07	2244	2596	0	2244	2596
Lactic acid	85.00	1381	1598	10	1243	1438
Propionic acid	103.38	1680	1944	0	1680	1944
Propylene glycol	124.34	2021	2338	0	2021	2338
Glycerol	97.83	1590	1839	30	1113	1287
Glucose	90.00	1463	1692	30	1024	1184
Sucrose	94.74	1539	1781	30	1078	1247
Starch	100.00	1625	1880	25	1219	1410

10.5.1.3 NE_{2015}, EW_{2015}, MEpo, MEla, and MEbr values of organic acids, glucose, sucrose and starch

	ATP yield relative to starch (%)	NE_{2015} (MJ/kg)	EW_{2015}	OEpl = OElh = OEvlk (MJ/kg)
Ethanol	146.74	20.75	2.36	25.42
Malic acid	57.09	8.07	0.92	9.89
Acetic acid	75.00	10.61	1.21	12.99
Buteric acid	138.07	19.52	2.22	23.91
Citric acid	60.94	8.62	0.98	10.55
Fumaric acid	65.95	9.33	1.06	11.42
Lactic acid	85.00	12.02	1.37	14.72
Propionic acid	103.38	14.62	1.66	17.91
Propylene glycol	124.34	17.58	2.00	21.54
Glycerol	97.83	13.83	1.57	16.94
Glucose	90.00	12.73	1.45	15.59
Sucrose	94.74	13.40	1.52	16.41
Starch	100.00	14.14	1.61	17.32

10.5.2 Energy value amino acids

Amino acid *	mol ATP/ mol AA according Van Milgen (2002)	ATP yielding capacity relative to starch	NE_{2015} at NE_{2015} Sta = 14.14 MJ/kg	EW_{2015} at NE_{2015} Sta = 14.14 MJ/kg and EW_{2015} = NE_{2015}/8.8	MEpo, MEla, MEbr at ME DNFE = 17.32 MJ/kg
LYS	37	114	16.13	1.83	19.75
MET	29,5	89	12.60	1.43	15.43
THR	22	83	11.76	1.34	14.41
TRP	45	99	14.04	1.60	17.19
ILE	41	1.41	19.91	2.26	24.39
ARG	29	75	10.61	1.21	12.99
LEU	40	137	19.43	2.21	23.80
VAL	32	123	17.40	1.98	21.32
GLY	7	42	5.94	0.67	7.27

*: The energy values are valid for the pure products; for commercial products the energy values presented in this Table must be corrected for the inclusion percentage in the commercial product. For example; Lysine-HCl contains 78% LYS; the energy value of LYS shown in this Table must then be multiplied with the factor 0.78.

10.5.3 Protein value miscellaneous products

10.5.1.2.1 Protein value of urea in the DVE/OEB 1991 system

Product	CP g/kg	DVE g/kg	OEB g/kg
Urea (100 %) [a]	2920 [b]	0	2920

a) Based on the purity of the commercial product the values shown in this Table should be adapted.
b) Based on N (= 46,6 %) x 6.25.
